- ♦ Angel, sections 8.1 - 8.6
- ♦ *OpenGL Programming Guide*, chapter 3

## 10. Hierarchical Modeling

1

2

## Symbols and instances

Most graphics APIs support a few geometric **primitives**:

- ♦ spheres
- ♦ cubes
- ♦ cylinders

These symbols are **instanced** using an **instance transformation**.

**Q:** What is the matrix for the instance transformation above?

3

## Connecting primitives

4

## 3D Example: A robot arm

Consider this robot arm with 3 degrees of freedom:

- ◆ Base rotates about its vertical axis by  $\theta$
- ◆ Upper arm rotates in its  $xy$ -plane by  $\phi$
- ◆ Lower arm rotates in its  $xy$ -plane by  $\psi$

**Q:** What matrix do we use to transform the base?

**Q:** What matrix for the upper arm?

**Q:** What matrix for the lower arm?

5

## Robot arm implementation

The robot arm can be displayed by keeping a global matrix and computing it at each step:

```
Matrix M_model;

main()
{
    . . .
    robot_arm();
    . . .
}

robot_arm()
{
    M_model = R_y(theta);
    base();
    M_model = R_y(theta)*T(0,h1,0)*R_z(phi);
    upper_arm();
    M_model = R_y(theta)*T(0,h1,0)*R_z(phi)
                *T(0,h2,0)*R_z(psi);
    lower_arm();
}
```

Do the matrix computations seem wasteful?

6

## Robot arm implementation, better

Instead of recalculating the global matrix each time, we can just update it *in place* by concatenating matrices on the right:

```
Matrix M_model;

main()
{
    . . .
    M_model = Identity();
    robot_arm();
    . . .
}

robot_arm()
{
    M_model *= R_y(theta);
    base();
    M_model *= T(0,h1,0)*R_z(phi);
    upper_arm();
    M_model *= T(0,h2,0)*R_z(psi);
    lower_arm();
}
```

7

## Robot arm implementation, OpenGL

OpenGL maintains a global state matrix called the **model-view matrix**, which is updated by concatenating matrices on the right.

```
main()
{
    . . .
    glMatrixMode( GL_MODELVIEW );
    glLoadIdentity();
    robot_arm();
    . . .
}

robot_arm()
{
    glRotatef( theta, 0.0, 1.0, 0.0 );
    base();
    glTranslatef( 0.0, h1, 0.0 );
    glRotatef( phi, 0.0, 0.0, 1.0 );
    lower_arm();
    glTranslatef( 0.0, h2, 0.0 );
    glRotatef( psi, 0.0, 0.0, 1.0 );
    upper_arm();
}
```

8

## Hierarchical modeling

Hierarchical models can be composed of instances using trees or DAGs:

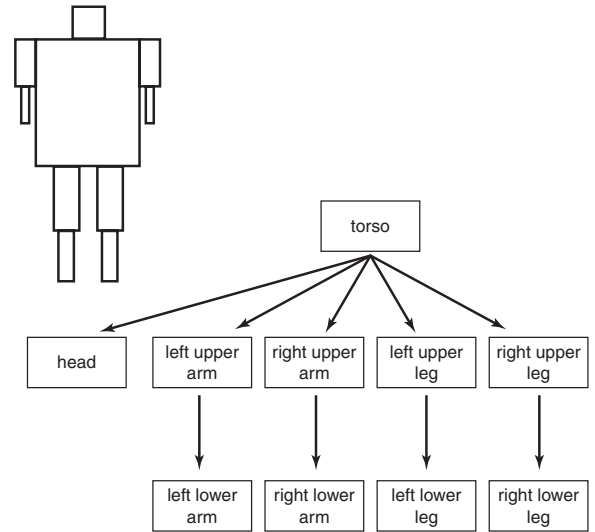

- ◆ edges contain geometric transformations
- ◆ nodes contain geometry (and possibly drawing attributes)

How might we draw the tree for the robot arm?

9

## A complex example: human figure

**Q:** What's the most sensible way to traverse this tree?

10

## Human figure implementation, OpenGL

```

figure()
{
    torso();
    glPushMatrix();
        glTranslate( ... );
        glRotate( ... );
        head();
    glPopMatrix();
    glPushMatrix();
        glTranslate( ... );
        glRotate( ... );
        left_upper_arm();
        glPushMatrix();
            glTranslate( ... );
            glRotate( ... );
            left_lower_arm();
        glPopMatrix();
    glPopMatrix();
    . . .
}
    
```

11

## Animation

The above examples are called **articulated models**:

- ◆ rigid parts
- ◆ connected by joints

They can be animated by specifying the joint angles (or other display parameters) as functions of time.

12

## Key-frame animation

The most common method for character animation in production is **key-frame animation**.

- ◆ Each joint specified at various **key frames** (not necessarily the same as other joints)
- ◆ System does interpolation or **in-betweening**

Doing this well requires:

- ◆ A way of smoothly interpolating key frames: **splines**
- ◆ A good interactive system
- ◆ A lot of skill on the part of the animator

13

## Scene graphs

The idea of hierarchical modeling can be extended to an entire scene, encompassing:

- ◆ many different objects
- ◆ lights
- ◆ camera position

This is called a **scene tree** or **scene graph**.
