**Aliasing in rendering**

One of the most common rendering artifacts is the “jaggies”. Consider rendering a white polygon against a black background:

![Aliasing example](image1)

We would instead like to get a smoother transition:

![Smoothening example](image2)

---

**Anti-aliasing**

Q: How do we avoid aliasing artifacts?

1. Sampling:
2. Pre-filtering:
3. Combination:

Example - polygon:

![Polygon example](image3)
Polygon anti-aliasing

Without antialiasing

With antialiasing

Magnification

Antialiasing in a ray tracer

We would like to compute the average intensity in the neighborhood of each pixel.

When casting one ray per pixel, we are likely to have aliasing artifacts.

To improve matters, we can cast more than one ray per pixel and average the result.

A.k.a., super-sampling and averaging down.

Temporal aliasing

Suppose we are rendering a “clock” with a fast turning hand:

What happens if we sample too infrequently? (This is sometimes called the “wagon wheel” effect.)

Another more common scenario is something moving quickly across the frame, e.g., a fast-moving particle:

How might we address these temporal aliasing effects?

Speeding it up

Brute force ray tracing is really slow!

Consider rendering a single image with:

- $m \times m$ pixels
- $k \times k$ supersampling
- $n$ primitives
- average ray path length of $d$
- $\ell$ shadow ray per intersection
- 0, 1, or 2 rays cast recursively per intersection

Asymptotic complexity =

For $m=1,000$, $k=5$, $n=100,000$, $\ell=10$, $d=8$…very expensive!!

In practice, some acceleration technique is almost always used.

We’ve already looked at reducing $d$ with adaptive (early) ray termination.

Now we look at reducing the effect of the $k$ and $n$ terms…
Antialiasing by adaptive sampling

Casting many rays per pixel can be unnecessarily costly. If there are no rapid changes in intensity at the pixel, maybe only a few samples are needed.

Solution: adaptive sampling.

Q: When do we decide to cast more rays in a particular area?

Faster ray-polyhedron intersection

Let’s say you were intersecting a ray with a polyhedron:

Q: How might you speed this up?

Hierarchical bounding volumes

We can generalize the idea of bounding volume acceleration with hierarchical bounding volumes.

Uniform spatial subdivision

Another approach is uniform spatial subdivision.

Idea:

- Partition space into cells (voxels)
- Associate each primitive with the cells it overlaps
- Trace ray through voxel array using fast incremental arithmetic to step from cell to cell
Non-uniform spatial subdivision

Still another approach is non-uniform spatial subdivision.

Other variants include k-d trees and BSP trees.

Various combinations of these ray intersections techniques are also possible. See Shirley, Glassner, and pointers at bottom of project web page for more.
