# CSE-571 Probabilistic Robotics

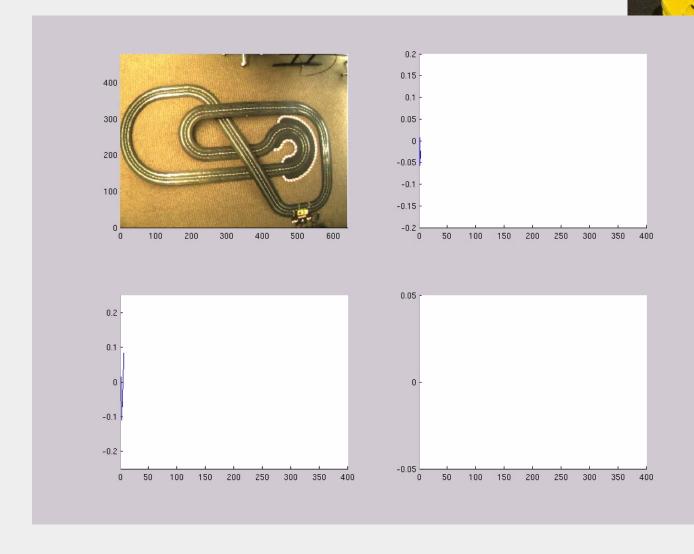

### **Probabilistic Sensor Models**

Beam-based Scan-based Landmarks

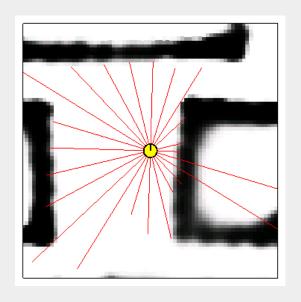

### **Sensors for Mobile Robots**

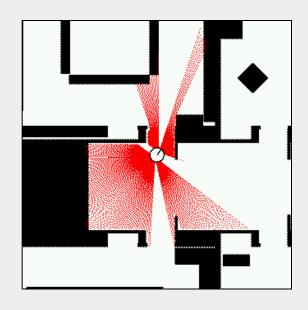

- Contact sensors: Bumpers
- Internal sensors
  - Accelerometers (spring-mounted masses)
  - Gyroscopes (spinning mass, laser light)
  - Compasses, inclinometers (earth magnetic field, gravity)
- Proximity sensors
  - Sonar (time of flight)
  - Radar (phase and frequency)
  - Laser range-finders (triangulation, tof, phase)
  - Infrared (intensity)
- Visual sensors: Cameras, depth cameras
- Satellite-based sensors: GPS

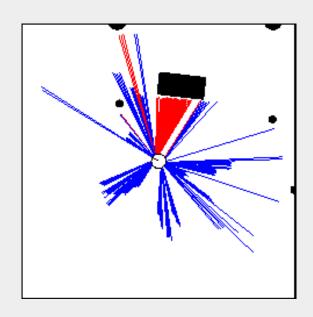

### **IMU on Slotcar**

# **Proximity Sensors**

- The central task is to determine P(z|x), i.e. the probability of a measurement z given that the robot is at position x.
- Question: Where do the probabilities come from?
- Approach: Let's try to explain a measurement.

### **Beam-based Sensor Model**

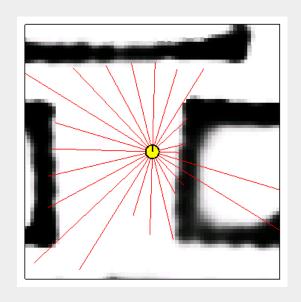

Scan z consists of K measurements.

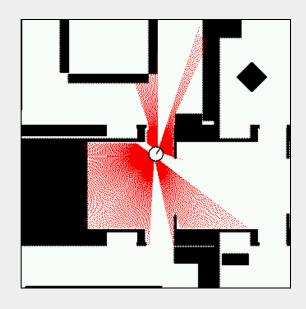

$$z = \{z_1, z_2, ..., z_K\}$$

 Individual measurements are independent given the robot position.

$$P(z \mid x, m) = \prod_{k=1}^{K} P(z_k \mid x, m)$$

### **Beam-based Sensor Model**

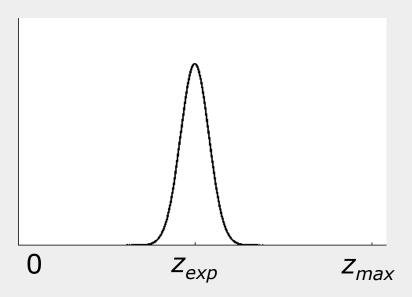

$$P(z | x, m) = \prod_{k=1}^{K} P(z_k | x, m)$$

# **Proximity Measurement**

- Measurement can be caused by ...
  - a known obstacle.
  - cross-talk.
  - an unexpected obstacle (people, furniture, ...).
  - missing all obstacles (total reflection, glass, ...).
- Noise is due to uncertainty ...
  - in measuring distance to known obstacle.
  - in position of known obstacles.
  - in position of additional obstacles.
  - whether obstacle is missed.

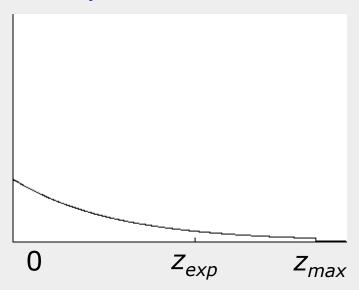

# **Beam-based Proximity Model**

#### Measurement noise

$$P_{hit}(z \mid x, m) = \eta \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2}\frac{(z-z_{\exp})^2}{\sigma^2}}$$

#### Unexpected obstacles

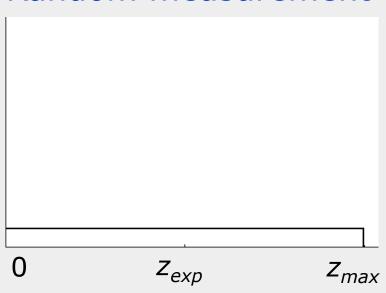

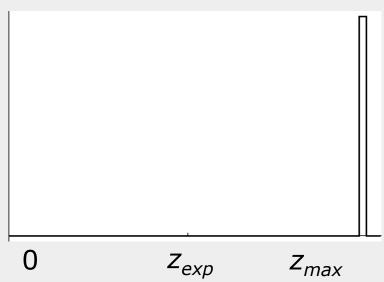

$$P_{\text{unexp}}(z \mid x, m) = \eta \lambda e^{-\lambda z}$$

# **Beam-based Proximity Model**

#### Random measurement

### Max range

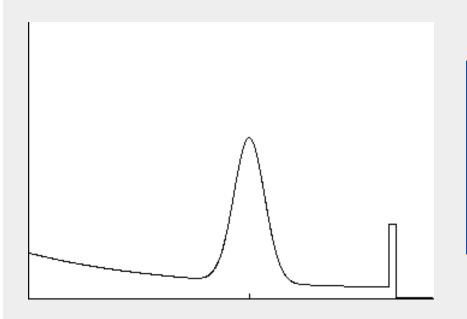

$$P_{rand}(z \mid x, m) = \eta \frac{1}{z_{\text{max}}}$$

$$P_{\max}(z \mid x, m) = \eta \frac{1}{z_{small}}$$

# **Mixture Density**

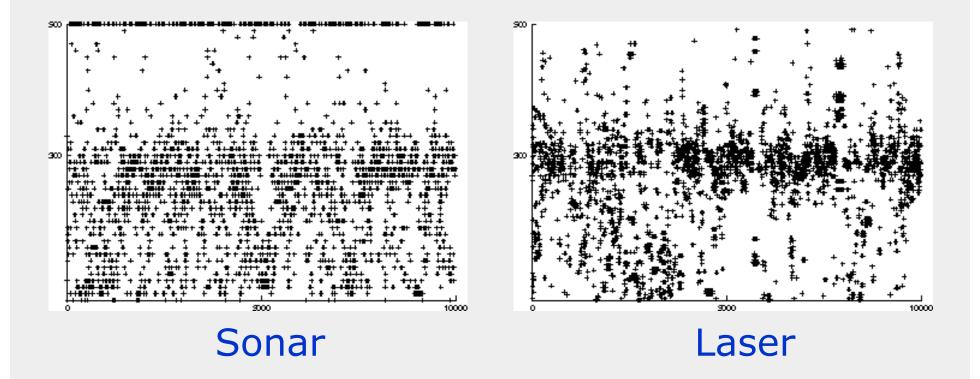

$$P(z \mid x, m) = \begin{pmatrix} \alpha_{\text{hit}} \\ \alpha_{\text{unexp}} \\ \alpha_{\text{max}} \\ \alpha_{\text{rand}} \end{pmatrix} \cdot \begin{pmatrix} P_{\text{hit}}(z \mid x, m) \\ P_{\text{unexp}}(z \mid x, m) \\ P_{\text{max}}(z \mid x, m) \\ P_{\text{rand}}(z \mid x, m) \end{pmatrix}$$

How can we determine the model parameters?

### **Raw Sensor Data**

Measured distances for expected distance of 300 cm.

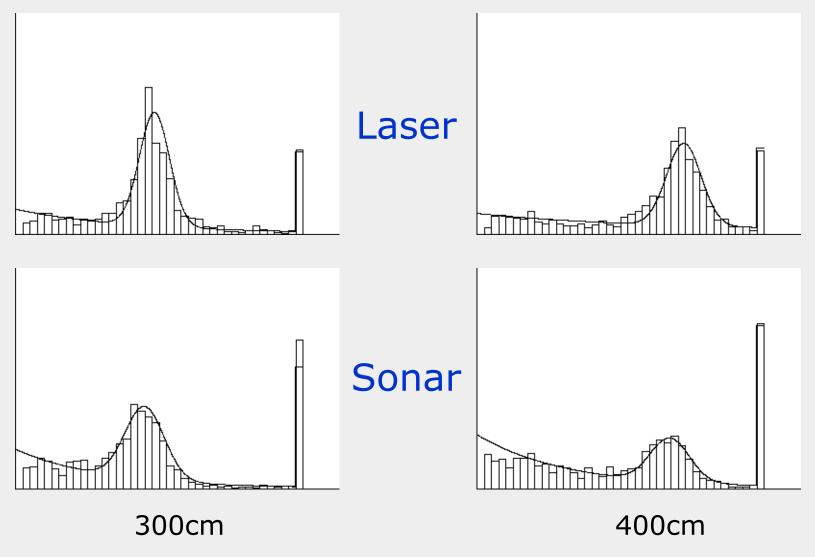

# **Approximation**

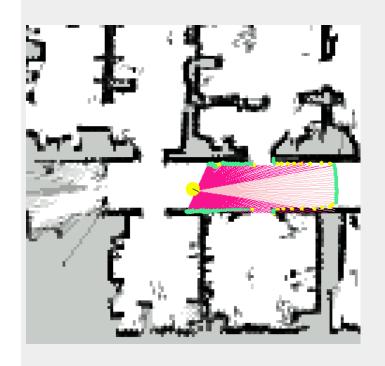

• Maximize log likelihood of the data  $P(z \mid z_{\rm exp})$ 

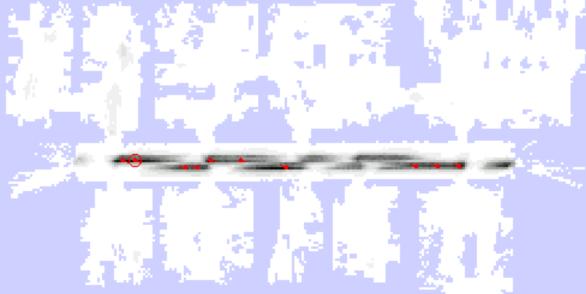

- Search parameter space.
- EM to find mixture parameters
  - Assign measurements to densities.
  - Estimate densities using assignments.
  - Reassign measurements.

# **Approximation Results**

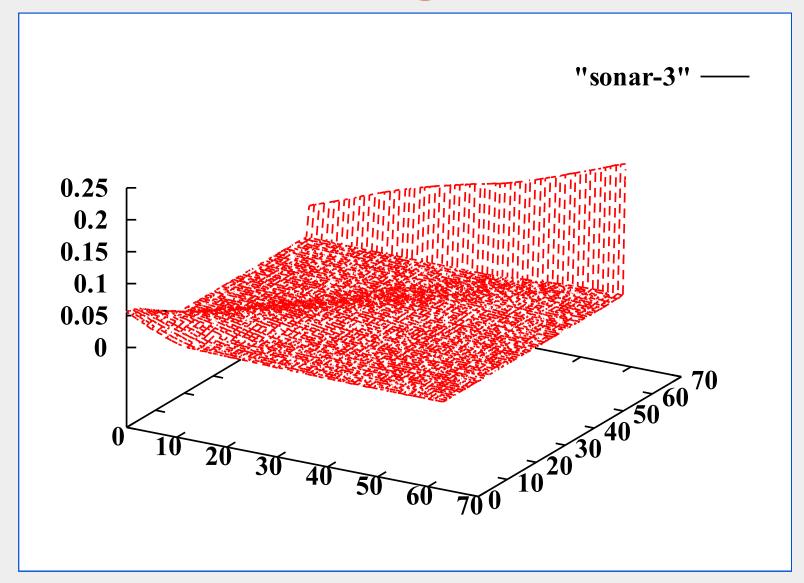

# **Example**

Z

# **Influence of Angle to Obstacle**

# **Summary Beam-based Model**

- Assumes independence between beams.
  - Justification?
  - Overconfident!
- Models physical causes for measurements.
  - Mixture of densities for these causes.
- Implementation
  - Learn parameters based on real data.
  - Different models should be learned for different angles at which the sensor beam hits the obstacle.
  - Determine expected distances by ray-tracing.
  - Expected distances can be pre-processed.

### **Scan-based Model**

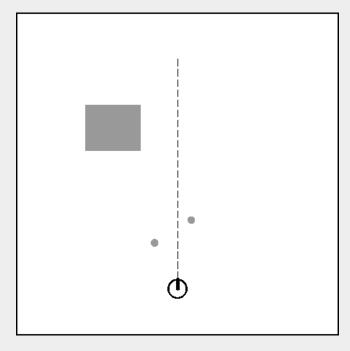

- Beam-based model is ...
  - not smooth for small obstacles and at edges.
  - not very efficient.

• Idea: Instead of following along the beam, just check the end point.

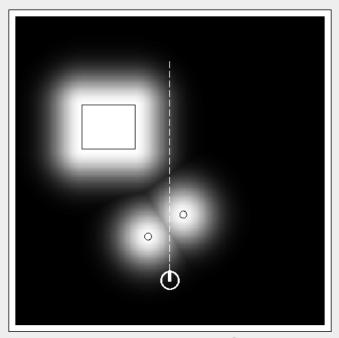

### **Scan-based Model**

- Probability is a mixture of ...
  - a Gaussian distribution with mean at distance to closest obstacle,
  - a uniform distribution for random measurements, and
  - a small uniform distribution for max range measurements.
- Again, independence between different components is assumed.

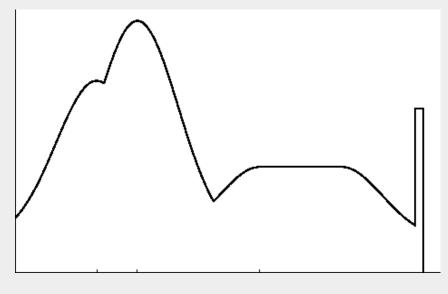

# **Example**

Map m

Likelihood field

### San Jose Tech Museum

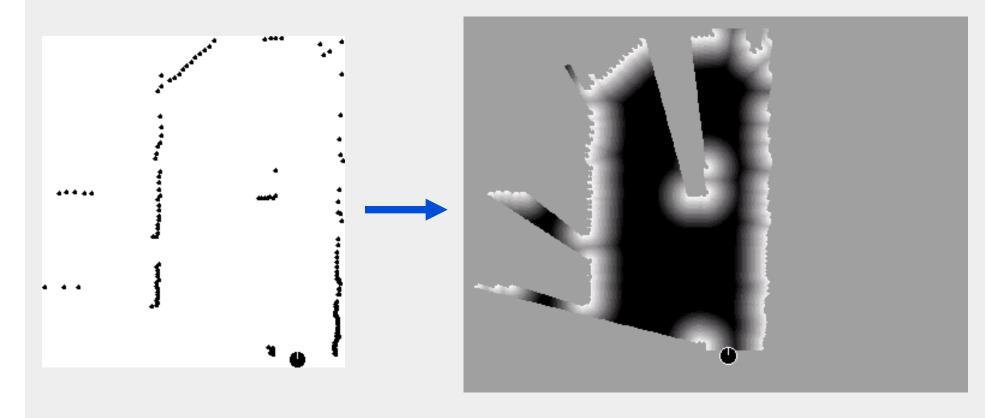

Occupancy grid map

Likelihood field

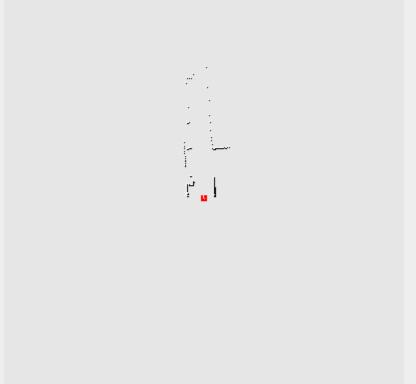

### **Scan Matching**

 Extract likelihood field from scan and use it to match different scan.

# **Scan Matching**

 Extract likelihood field from first scan and use it to match second scan.

~0.01 sec

# **Properties of Scan-based Model**

- Highly efficient, uses 2D tables only.
- Smooth w.r.t. to small changes in robot position.
- Allows gradient descent, scan matching.
- Ignores physical properties of beams.
- Works for sonars?

### **Additional Models of Proximity Sensors**

- Map matching (sonar, laser): generate small, local maps from sensor data and match local maps against global model.
- Scan matching (laser): map is represented by scan endpoints, match scan into this map using ICP, correlation.
- Features (sonar, laser, vision): Extract features such as doors, hallways from sensor data.

### Landmarks

- Active beacons (e.g. radio, GPS)
- Passive (e.g. visual, retro-reflective)
- Standard approach is triangulation
- Sensor provides
  - distance, or
  - bearing, or
  - distance and bearing.

# **Distance and Bearing**

### **Probabilistic Model**

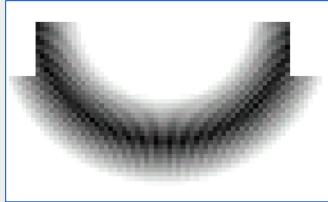

1. Algorithm landmark\_detection\_model(z,x,m):  $z = \langle i, d, \alpha \rangle, x = \langle x, y, \theta \rangle$ 

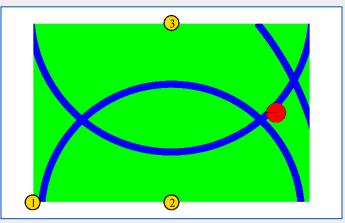

2. 
$$\hat{d} = \sqrt{(m_x(i) - x)^2 + (m_y(i) - y)^2}$$

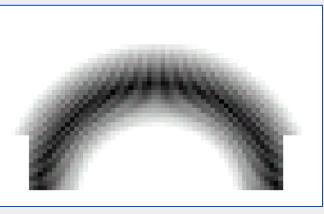

- 3.  $\hat{a} = \text{atan2}(m_y(i) y, m_x(i) x) \theta$
- 4.  $p_{\text{det}} = \text{prob}(\hat{d} d, \varepsilon_d) \cdot \text{prob}(\hat{\alpha} \alpha, \varepsilon_\alpha)$
- 5. Return  $z_{\text{det}} p_{\text{det}} + z_{\text{fp}} P_{\text{uniform}}(z \mid x, m)$

# Distributions for P(z|x)

### **Summary of Sensor Models**

- Explicitly modeling uncertainty in sensing is key to robustness.
- In many cases, good models can be found by the following approach:
  - 1. Determine parametric model of noise free measurement.
  - 2. Analyze sources of noise.
  - 3. Add adequate noise to parameters (eventually mix in densities for noise).
  - 4. Learn (and verify) parameters by fitting model to data.
  - 5. Likelihood of measurement is given by "probabilistically comparing" the actual with the expected measurement.
- This holds for motion models as well.
- It is extremely important to be aware of the underlying assumptions!
