## Motion Planning: Outline

- Configuration Space
- Probabilistic Roadmap
- Rapidly-exploring Random Trees (RRTs)
- Extensions
- Smoothing

## Configuration Space (C-Space)

Any configuration of a robot can be described as a unique point in its configuration space (C-space)

## Configuration Space (C-Space)

Any configuration of a robot can be described as a unique point in its configuration space (C-space)

## Motion planning

## Motion planning

## Probabilistic Roadmap (PRM)

## Probabilistic Roadmap (PRM)

Configurations are sampled by picking coordinates at random

## Probabilistic Roadmap (PRM)

Configurations are sampled by picking coordinates at random

## Probabilistic Roadmap (PRM)

Sampled configurations are tested for collision

## Probabilistic Roadmap (PRM)

The collision-free configurations are retained as **milestones**

## Probabilistic Roadmap (PRM)

Each milestone is linked by straight paths to its nearest neighbors

## Probabilistic Roadmap (PRM)

Each milestone is linked by straight paths to its nearest neighbors

## Probabilistic Roadmap (PRM)

The collision-free links are retained as **local paths** to form the PRM

## Probabilistic Roadmap (PRM)

The start and goal configurations are included as milestones

## Probabilistic Roadmap (PRM)

The PRM is searched for a path from s to g

## Probabilistic Roadmap (PRM)

```

1: for  $i = 1, \dots, N$  do
2:    $q_i \leftarrow$  sample from  $\mathcal{C}_{free}$ 
3:   add  $q_i$  to Roadmap  $R$ 
4: end for
5: for  $i = 1, \dots, N$  do
6:    $\mathcal{N}(q_i) \leftarrow k$  closest neighbors of  $q_i$ 
7:   for each  $q \in \mathcal{N}(q_i)$  do
8:     if there is a collision free local path from  $q$  to  $q_i$  and there is not already
       an edge from  $q$  to  $q_i$  then
9:       add an edge from  $q$  to  $q_i$  to the Roadmap  $R$ 
10:    end if
11:  end for
12: end for
13: return  $R$ 

```

## Probabilistic Roadmap (PRM)

```

1: for  $i = 1, \dots, N$  do
2:    $q_i \leftarrow$  sample from  $\mathcal{C}_{free}$ 
3:   add  $q_i$  to Roadmap  $R$ 
4: end for
5: for  $i = 1, \dots, N$  do
6:    $\mathcal{N}(q_i) \leftarrow k$  closest neighbors of  $q_i$ 
7:   for each  $q \in \mathcal{N}(q_i)$  do
8:     if there is a collision free local path from  $q$  to  $q_i$  and there is not already
       an edge from  $q$  to  $q_i$  then
9:       add an edge from  $q$  to  $q_i$  to the Roadmap  $R$ 
10:    end if
11:  end for
12: end for
13: return  $R$ 

```

The resulting  $R$  depends on:

- $N$  - number of samples
- $k$  - number of neighbors
- Sampler
- Local path planner

## Probabilistic Roadmap (PRM)

```

1: for  $i = 1, \dots, N$  do
2:    $q_i \leftarrow$  sample from  $\mathcal{C}_{free}$ 
3:   add  $q_i$  to Roadmap  $R$ 
4: end for
5: for  $i = 1, \dots, N$  do
6:    $\mathcal{N}(q_i) \leftarrow k$  closest neighbors of  $q_i$ 
7:   for each  $q \in \mathcal{N}(q_i)$  do
8:     if there is a collision free local path from  $q$  to  $q_i$  and there is not already
       an edge from  $q$  to  $q_i$  then
9:       add an edge from  $q$  to  $q_i$  to the Roadmap  $R$ 
10:    end if
11:  end for
12: end for
13: return  $R$ 

```

The resulting  $R$  depends on:

- $N$  - number of samples
- $k$  - number of neighbors
- Sampler
- Local path planner

PRM is a multiple-query planner: invest time in generating a good representation of the free C-space, that can be used to solve several motion planning problems.

## Probabilistic Roadmap (PRM)

Demonstration - <https://demonstrations.wolfram.com/ProbabilisticRoadmapMethodForRobotArm/>

## PRM Example 1

## PRM Example 2

## PRM's Pros and Cons

- Pro:
  - Probabilistically complete: i.e., with probability one, if run for long enough the graph will contain a solution path if one exists.
- Cons:
  - Required to solve 2-point boundary value problem
  - Build graph over state space but no focus on generating a path

## Rapidly exploring Random Tree (RRT)

Steve LaValle (98)

- Basic idea:
  - Build up a tree through generating “next states” in the tree by executing random controls
  - However: not exactly above to ensure good coverage

Demonstration - <https://demonstrations.wolfram.com/RapidlyExploringRandomTreeRRTAndRRT/>

## Rapidly exploring Random Tree (RRT)

- Select random point, and expand nearest vertex towards it
  - Biases samples towards largest Voronoi region

## Rapidly exploring Random Tree (RRT)

- Select random point, and expand nearest vertex towards it
  - Biases samples towards largest Voronoi region

## Rapidly exploring Random Tree (RRT)

Source: LaValle and Kuffner 01

## Rapidly exploring Random Tree (RRT)

GENERATE\_RRT( $x_{init}, K, \Delta t$ )

```

1   $\mathcal{T}.init(x_{init});$ 
2  for  $k = 1$  to  $K$  do
3     $x_{rand} \leftarrow \text{RANDOM\_STATE}();$ 
4     $x_{near} \leftarrow \text{NEAREST\_NEIGHBOR}(x_{rand}, \mathcal{T});$ 
5     $u \leftarrow \text{SELECT\_INPUT}(x_{rand}, x_{near});$ 
6     $x_{new} \leftarrow \text{NEW\_STATE}(x_{near}, u, \Delta t);$ 
7     $\mathcal{T}.add\_vertex(x_{new});$ 
8     $\mathcal{T}.add\_edge(x_{near}, x_{new}, u);$ 
9  Return  $\mathcal{T}$ 
    
```

RANDOM\_STATE(): often uniformly at random over space with probability 99%, and the goal state with probability 1%, this ensures it attempts to connect to goal semi-regularly

## RRT Practicalities

- $\text{NEAREST\_NEIGHBOR}(x_{\text{rand}}, T)$ : need to find (approximate) nearest neighbor efficiently
  - KD Trees data structure (upto 20-D) [e.g., FLANN]
  - Locality Sensitive Hashing
- $\text{SELECT\_INPUT}(x_{\text{rand}}, x_{\text{near}})$ 
  - Two point boundary value problem
    - If too hard to solve, often just select best out of a set of control sequences. This set could be random, or some well chosen set of primitives.

## RRT Extension

- Non-holonomic: approximately (sometimes as approximate as picking best of a few random control sequences) solve two-point boundary value problem

## RRT Extension

- Non-holonomic: approximately (sometimes as approximate as picking best of a few random control sequences) solve two-point boundary value problem

## RRT Extension

- Non-holonomic: approximately (sometimes as approximate as picking best of a few random control sequences) solve two-point boundary value problem

## Bi-directional RRT

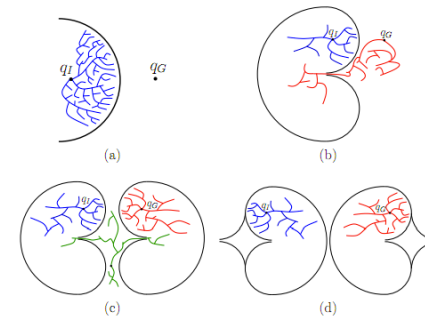

- Volume swept out by unidirectional RRT:
- Volume swept out by bi-directional RRT:

- Difference more and more pronounced as dimensionality increases

## Multi-directional RRT

- Planning around obstacles or through narrow passages can often be easier in one direction than the other

## RRT\*

### Algorithm 6: RRT\*

```

1  $V \leftarrow \{x_{init}\}; E \leftarrow \emptyset;$ 
2 for  $i = 1, \dots, n$  do
3    $x_{rand} \leftarrow \text{SampleFree}_i;$ 
4    $x_{nearest} \leftarrow \text{Nearest}(G = (V, E), x_{rand});$ 
5    $x_{new} \leftarrow \text{Steer}(x_{nearest}, x_{rand});$ 
6   if  $\text{ObstacleFree}(x_{nearest}, x_{new})$  then
7      $x_{near} \leftarrow \text{Near}(G = (V, E), x_{new}, \min\{\gamma_{RRT^*}(\log(\text{card}(V)) / \text{card}(V))^{1/d}, \eta\});$ 
8      $V \leftarrow V \cup \{x_{new}\};$ 
9      $x_{min} \leftarrow x_{nearest}; c_{min} \leftarrow \text{Cost}(x_{nearest}) + c(\text{Line}(x_{nearest}, x_{new}));$ 
10    foreach  $x_{near} \in X_{near}$  do // Connect along a minimum-cost path
11      if  $\text{CollisionFree}(x_{near}, x_{new}) \wedge \text{Cost}(x_{near}) + c(\text{Line}(x_{near}, x_{new})) < c_{min}$  then
12         $x_{min} \leftarrow x_{near}; c_{min} \leftarrow \text{Cost}(x_{near}) + c(\text{Line}(x_{near}, x_{new}));$ 
13     $E \leftarrow E \cup \{(x_{min}, x_{new})\};$ 
14    foreach  $x_{near} \in X_{near}$  do // Rewire the tree
15      if  $\text{CollisionFree}(x_{new}, x_{near}) \wedge \text{Cost}(x_{new}) + c(\text{Line}(x_{new}, x_{near})) < \text{Cost}(x_{near})$ 
16        then  $x_{parent} \leftarrow \text{Parent}(x_{near});$ 
17         $E \leftarrow (E \setminus \{(x_{parent}, x_{near})\}) \cup \{(x_{new}, x_{near})\}$ 
18 return  $G = (V, E);$ 

```

Same as RRT

Find the set of neighbors to  $x_{new}$  in the  $G$   
Add  $x_{new}$  to  $G$

Find a neighbor from the set that will lead to  $x_{new}$  at less cost.  
Add an edge to that neighbor and  $x_{new}$

Rewire the set of neighbors with edges such that cost to reach any of these nodes from the root is minimum while the new node  $x_{new}$

## RRT\*

- Asymptotically optimal
- Main idea:
  - Swap new point in as parent for nearby vertices who can be reached along shorter path through new point than through their original (current) parent

(a) RRT\* run 1

(b) RRT\* run 1

## Smoothing

Randomized motion planners tend to find not so great paths for execution: very jagged, often much longer than necessary.

→ In practice: do smoothing before using the path

- **Shortcutting:**
  - along the found path, pick two vertices  $x_{i1}$ ,  $x_{i2}$  and try to connect them directly (skipping over all intermediate vertices)
- **Nonlinear optimization for optimal control**
  - Allows to specify an objective function that includes smoothness in state, control, small control inputs, etc.
