

Color

- Used heavily in human vision
- Color is a pixel property, making some recognition problems easy
- Visible spectrum for humans is 400nm (blue) to 700 nm (red)
- Machines can “see” much more; ex. X-rays, infrared, radio waves

1

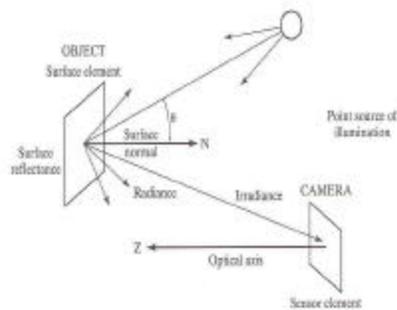

Factors that Affect Perception

- Light: the spectrum of energy that illuminates the object surface
- Reflectance: ratio of reflected light to incoming light
- Specularity: highly specular (shiny) vs. matte surface
- Distance: distance to the light source
- Angle: angle between surface normal and light source
- Sensitivity: how sensitive is the sensor

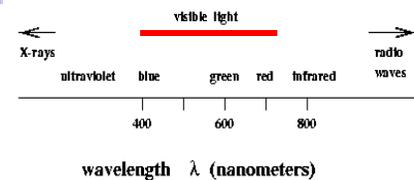

3

Imaging Process (review)

2

Some physics of color

- White light is composed of all visible frequencies (400-700)
- Ultraviolet and X-rays are of much smaller wavelength
- Infrared and radio waves are of much longer wavelength

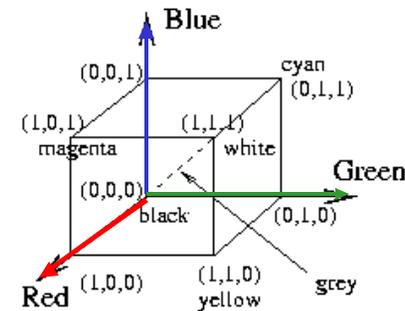

4

Coding methods for humans

- RGB is an additive system (add colors to black) used for displays
- CMY[K] is a subtractive system for printing
- HSV is good a good perceptual space for art, psychology, and recognition
- YIQ used for TV is good for compression

5

RGB color cube

- R, G, B values normalized to (0, 1) interval
- human perceives gray for triples on the diagonal
- "Pure colors" on corners

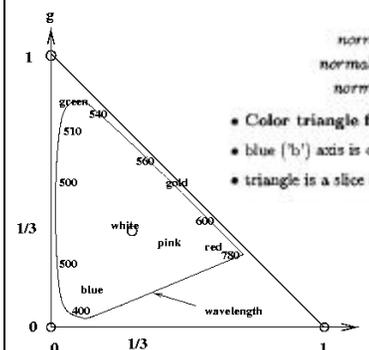

7

Comparing color codes

	RGB	CMY	HSI
RED	(255, 0, 0)	(0, 255, 255)	(0.0, 1.0, 255)
YELLOW	(255, 255, 0)	(0, 0, 255)	(1.05, 1.0, 255)
	(100, 100, 50)	(155, 155, 205)	(1.05, 0.5, 100)
GREEN	(0, 255, 0)	(255, 0, 255)	(2.09, 1.0, 255)
BLUE	(0, 0, 255)	(255, 255, 0)	(4.19, 1.0, 255)
WHITE	(255, 255, 255)	(0, 0, 0)	(-1.0, 0.0, 255)
GREY	(192, 192, 192)	(63, 63, 63)	(-1.0, 0.0, 192)
	(127, 127, 127)	(128, 128, 128)	(-1.0, 0.0, 127)
	(63, 63, 63)	(192, 192, 192)	(-1.0, 0.0, 63)
...			
BLACK	(0, 0, 0)	(255, 255, 255)	(-1.0, 0.0, 0)

- convenient to scale values in the range 0 to 1 in algorithms
- HSI values are computed from RGB values using Alg.
- $H \in [0, 2\pi)$, $S \in [0, 1.0]$ and $I \in [0, 255]$
- Equal proportion of RGB yield grey.
- Equal proportion of R and G yield yellow.

Color palette and normalized RGB

$$\text{intensity } I = (R + G + B)/3$$

$$\text{normalized red } r = R/(R + G + B)$$

$$\text{normalized green } g = G/(R + G + B)$$

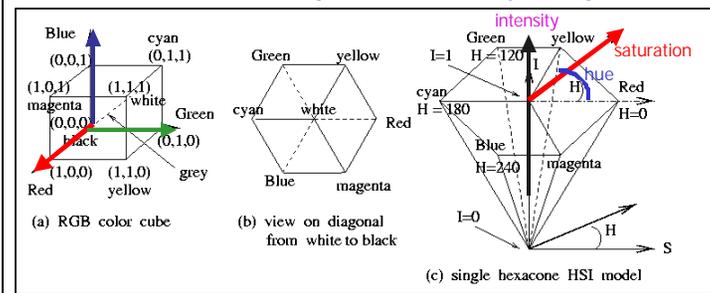

$$\text{normalized blue } b = B/(R + G + B)$$

- Color triangle for normalized RGB coordinates.
- blue ('b') axis is out of page perpendicular to 'r' and 'g' axes.
- triangle is a slice through the points [1,0,0], [0,1,0], [0,0,1].

8

Color hexagon for HSI (HSV)

Color is coded relative to the diagonal of the color cube. Hue is encoded as an angle, saturation is the relative distance from the diagonal, and intensity is height.

Properties of HSI (HSV)

- Separates out intensity **I** from the coding
- Two values (**H** & **S**) encode *chromaticity*
- Convenient for *designing* colors
- Hue **H** is defined by an angle
- Saturation **S** models the *purity* of the color
 - $S=1$ for a completely pure or saturated color
 - $S=0$ for a shade of "gray"

11

Editing saturation of colors

(Left) Image of food originating from a digital camera;
 (center) saturation value of each pixel decreased 20%;
 (right) saturation value of each pixel increased 40%.

10

YIQ and YUV for TV signals

- Have better compression properties
- Luminance **Y** encoded using more bits than chrominance values **I** and **Q**; humans more sensitive to **Y** than **I, Q**
- NTSC TV uses luminance **Y**; chrominance values **I** and **Q**
- Luminance used by black/white TVs
- All 3 values used by color TVs
- YUV encoding used in some digital video and JPEG and MPEG compression

12

Conversion from RGB to YIQ

- An approximate linear transformation from RGB to YIQ is

$$\begin{aligned} \text{luminance } Y &= 0.30R + 0.59G + 0.11B \\ R - \text{cyan } I &= 0.60R - 0.28G - 0.32B \\ \text{magenta} - \text{green } Q &= 0.21R - 0.52G + 0.31B \end{aligned}$$

We often use this for color to gray-tone conversion.

13

Color Clustering by K-means Algorithm

Form K-means clusters from a set of n-dimensional vectors

1. Set i_c (iteration count) to 1
2. Choose randomly a set of K means $m_1(1), \dots, m_K(1)$.
3. For each vector x_i , compute $D(x_i, m_k(i_c))$, $k=1, \dots, K$ and assign x_i to the cluster C_j with nearest mean.
4. Increment i_c by 1, update the means to get $m_1(i_c), \dots, m_K(i_c)$.
5. Repeat steps 3 and 4 until $C_k(i_c) = C_k(i_c+1)$ for all k .

15

Colors can be used for image segmentation into regions

- Can cluster on color values and pixel locations
- Can use connected components and an approximate color criteria to find regions
- Can train an algorithm to look for certain colored regions – for example, skin color

14

K-means Clustering Example

Original RGB Image

Color Clusters by K-Means

16

Extracting "white regions"

- Program learns white from training set of sample pixels.
- Aggregate similar neighbors to form regions.
- Components might be classified as characters.
- (Work contributed by David Moore.)

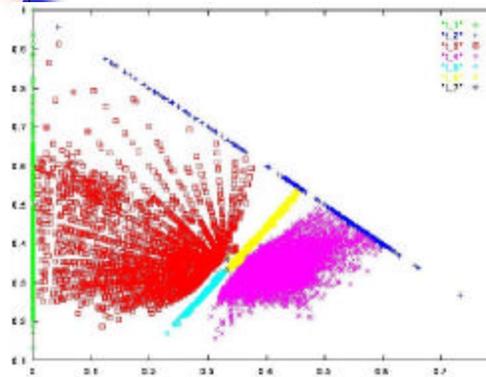

(Left) input RGB image

(Right) output is a labeled image.

Skin color in RGB space

Purple region shows skin color samples from several people. Blue and yellow regions show skin in shadow or behind a beard.

18

Finding a face in video frame

- (left) input video frame
- (center) pixels classified according to RGB space
- (right) largest connected component with aspect similar to a face (all work contributed by Vera Bakic)

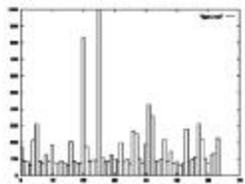

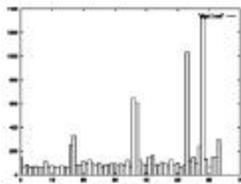

19

Color histograms can represent an image

- Histogram is fast and easy to compute.
- Size can easily be normalized so that different image histograms can be compared.
- Can match color histograms for database query or classification.

20

Histograms of two color images

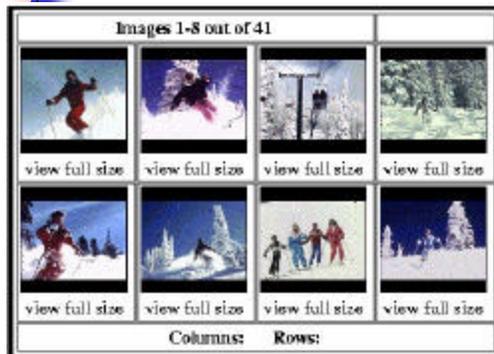

21

How to make a color histogram

- Make 3 histograms and concatenate them
- Create a single pseudo color between 0 and 255 by using 3 bits of R, 3 bits of G and 2 bits of B (which bits?)
- Can normalize histogram to hold frequencies so that bins total 1.0

23

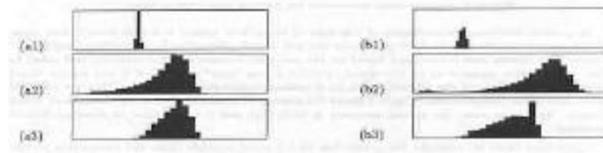

Retrieval from image database

Top left image is query image. The others are retrieved by having similar color histogram (See Ch 8).

22

Apples versus oranges

Separate HSI histograms for apples (left) and oranges (right) used by IBM's VeggieVision for recognizing produce at the grocery store checkout station (see Ch 16).

24

Swain and Ballard's Histogram Matching for Color Object Recognition

Opponent Encoding:

- $wb = R + G + B$
- $rg = R - G$
- $by = 2B - R - G$

Histograms: $8 \times 16 \times 16 = 2048$ bins

Intersection of image histogram and model histogram:

$$\text{intersection}(h(I), h(M)) = \sum_{j=1}^{\text{numbins}} \min\{h(I)[j], h(M)[j]\}$$

Match score is the normalized intersection:

$$\text{match}(h(I), h(M)) = \frac{\text{intersection}(h(I), h(M))}{\sum_{j=1}^{\text{numbins}} h(M)[j]}$$

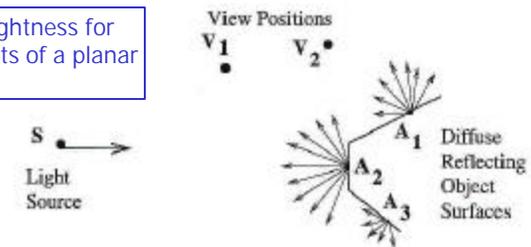

25

The Lambertian Model: Diffuse Surface Reflection

A diffuse reflecting surface reflects light uniformly in all directions

Uniform brightness for all viewpoints of a planar surface.

diffuse reflected $i \sim n_j \circ s$

Models of Reflectance

We need to look at models for the physics of illumination and reflection that will

1. help computer vision algorithms extract information about the 3D world, and
2. help computer graphics algorithms render realistic images of model scenes.

Physics-based vision is the subarea of computer vision that uses physical models to understand image formation in order to better analyze real-world images.

26

Real matte objects

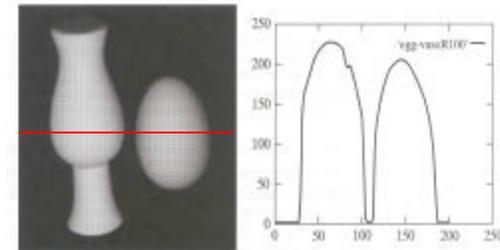

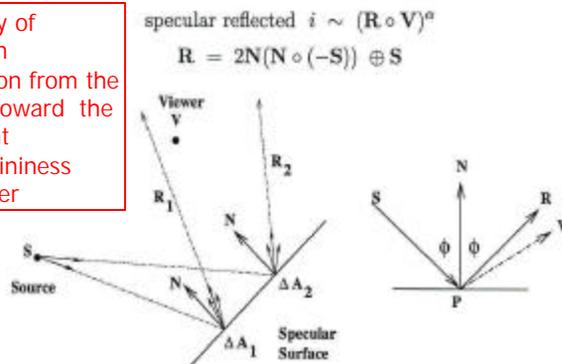

Figure 6.16 Diffuse reflection from Lambertian objects—a vase and an egg—and a plot of intensities across the highlighted row. The intensities are closely related to the object shape. (Image courtesy of Deborah Trytes.)

28

Specular reflection is highly directional and mirrorlike.

R is the ray of reflection
 V is direction from the surface toward the viewpoint
 α is the shininess parameter

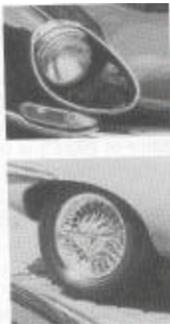

Phong reflection model

- Reasonable realism, reasonable computing
 - Uses the following components
 - ambient light
 - diffuse reflection component
 - specular reflection component
 - darkening with distance
- Components (b), (c), (d) are summed over all light sources.
- Modern computer games use more complicated models.

31

Real specular objects

- Chrome car parts are very shiny/mirrorlike
- So are glass or ceramic objects
- And waxey plant leaves

30

Phong shading model uses

- the reflective properties of surface elt imaging at $I[x, y]$
 - $K_{d\lambda}$ is diffuse reflectivity
 - $K_{s\lambda}$ for specular reflectivity
 - $K_{r\lambda}$ is a vector of coefficients of reflection for different wavelengths λ
- the position and characteristics of all M light sources

32

Phong model for intensity at wavelength lambda at pixel [x,y]

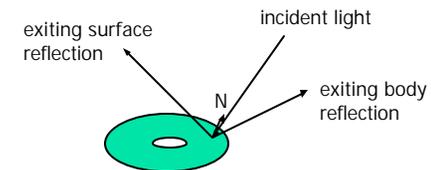

$$I_{\lambda}[x,y] = I_{a\lambda}K_{d\lambda} + \sum_{m=1}^M \left(\frac{1}{d_m^2} I_{m\lambda} [K_{d\lambda}(\mathbf{n} \circ \mathbf{s}_m) + K_{s\lambda}(\mathbf{R}_{m\lambda} \circ \mathbf{V})^\alpha] \right)$$

$I_{m\lambda}$ is the intensity of the light source m for wavelength λ . ($\mathbf{R}, \mathbf{G}, \mathbf{B}$)
The m -th light source is a distance d_m from the surface element and makes reflection ray $\mathbf{R}_{m\lambda}$ off the surface element.

33

The Dichromatic Reflection Model

The light reflected from a point on a dielectric non-uniform material is a mixture of the light reflected from the material **surface** and that from the material **body**.

35

Color Image Analysis with an Intrinsic Reflection Model*

The Problem:

- Understand the reflection properties of **dielectric** materials (e.g. plastics).
- Use them to separate highlights from true color of an object.
- Apply this to image segmentation.

*Klinker, Shafer, and Kanade, ICCV, 1988

34

Let $L(\lambda, i, e, g)$ be the total reflected light.

λ	wavelength
i	angle of incident light
e	angle of emitted light
g	phase angle

$$\text{Then } L(\lambda, i, e, g) = L_s(\lambda, i, e, g) + L_b(\lambda, i, e, g)$$

- The **surface reflection component** $L_s(\lambda, i, e, g)$ appears as a highlight or gloss.
- The **body reflection component** $L_b(\lambda, i, e, g)$ gives the characteristic object color.

36

The Dichromatic Reflection Equation

$$L(\lambda, i, e, g) = m_s(i, e, g)c_s(\lambda) + m_b(i, e, g)c_b(\lambda)$$

- c_s and c_b are the spectral power distributions
- m_s and m_b are the geometric scale factors

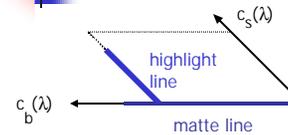

For RGB images, this reduces to the pixel equation

$$C = [R, G, B] = m_s C_s + m_b C_b$$

37

Dichromatic Plane

2 linear clusters

- matte points
- highlight points

- The combined color cluster looks like a **skewed T**.
- Skewing angle depends on color difference between body and surface reflection.
- As a heuristic, the highlight starts in the upper 50% of the matte line.

39

Object Shape and Color Variation

Assumption: all points on one object depend on the same color vectors $c_b(\lambda)$ and $c_s(\lambda)$. Then

- light mixtures all fall into a **dichromatic plane** in color space
- light mixtures form a dense **color cluster** in this plane

38

Color Image Analysis

- Color segmentation based on RGB will often find boundaries along highlights and shadows.
- The DRM can be used to better segment.

Algorithm:

1. compute initial rough segmentation

- **compute principal components** of color distribution from small, nonoverlapping image windows.
- **combine neighboring windows** with similar color distributions into larger regions of locally consistent color

40

2. For regions with linear descriptions

- approximate c_b by the first eigenvector of its color distribution
- construct a color cylinder with c_b as axis and width a multiple of estimated camera noise
- use the cylinder to decide which pixels to include in the image region
- result is a color segmentation that outlines the matte colors

41

3. Use the skewed T idea to find highlight clusters related to the matte clusters.
4. Use matte plus highlights to form the planar hypothesis.
5. Use the planar hypothesis to grow the matte linear object area into the highlight area.

See transparency for experimental results.

42
