Interest Operator Lectures

lecture topics

- Interest points 1 (Linda)
 - interest points, descriptors, Harris corners, correlation matching
- Interest points 2 (Linda)
 - Kadir operator, Fergus object recognition, Sivic video indexing
- Interest points 3 (Matt Brown from Microsoft Research: April 18)
 - improving feature matching and indexing, SIFT
- Image Stitching (Matt: April 23)
 - automatically combine multiple images to give seamless, "stitched" result

Interest Operators

- Find "interesting" pieces of the image
 - e.g. corners, salient regions
 - Focus attention of algorithms
 - Speed up computation
- Many possible uses in matching/recognition
 - Search
 - Object recognition
 - Image alignment & stitching
 - Stereo
 - Tracking
 - **–** ...

Interest points

0D structure

not useful for matching

1D structure

edge, can be localised in 1D, subject to the aperture problem

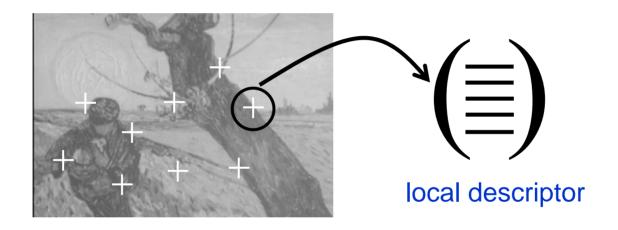

2D structure

corner, or interest point, can be localised in 2D, good for matching

Interest Points have 2D structure. Edge Detectors e.g. Canny [Canny86] exist, but descriptors are more difficult.

Local invariant photometric descriptors -

Local: robust to occlusion/clutter + no segmentation

Photometric: (use pixel values) distinctive descriptions

Invariant: to image transformations + illumination changes

History - Matching

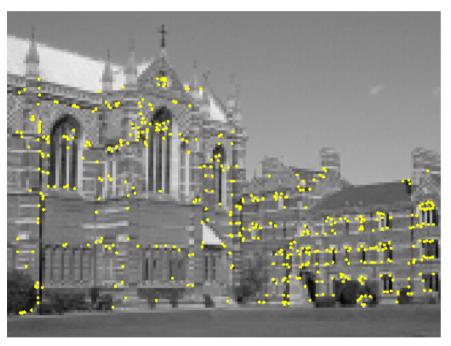

- 1. Matching based on correlation alone
- 2. Matching based on geometric primitives e.g. line segments
- ⇒ Not very discriminating (why?)
- ⇒ Solution : matching with interest points & correlation

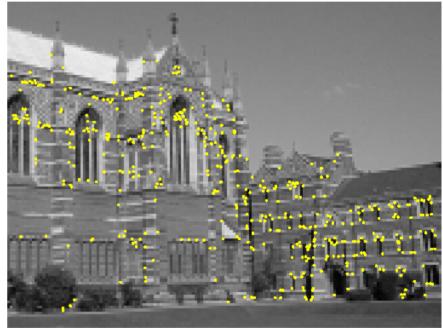

[A robust technique for matching two uncalibrated images through the recovery of the unknown epipolar geometry,

Z. Zhang, R. Deriche, O. Faugeras and Q. Luong, Artificial Intelligence 1995]

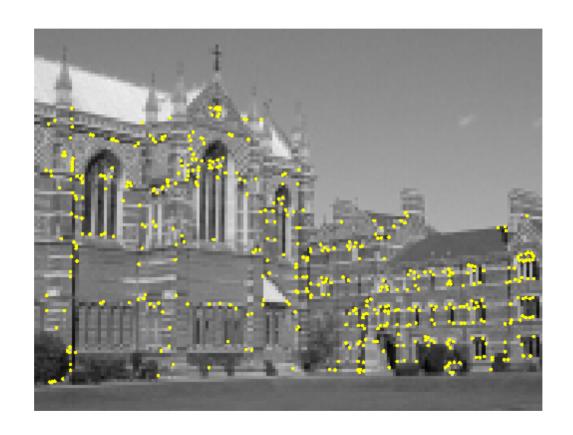

Approach

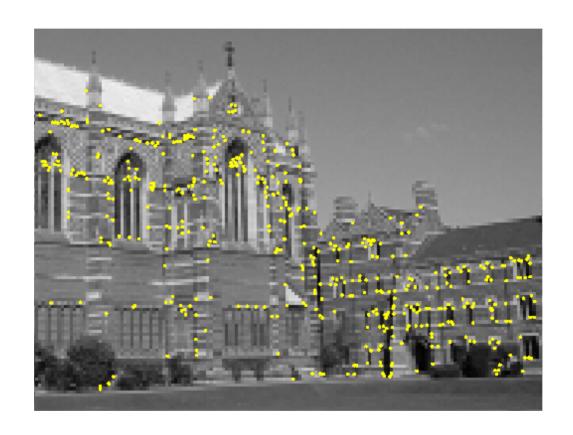

- Extraction of interest points with the Harris detector
- Comparison of points with cross-correlation
- Verification with the fundamental matrix

Interest points extracted with Harris (~ 500 points)

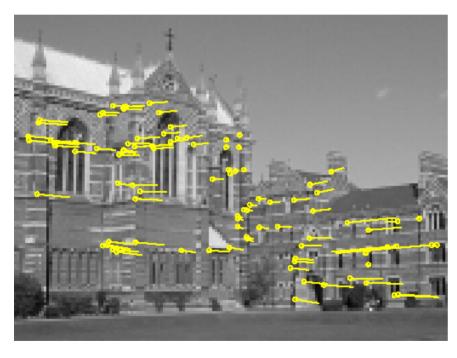

Cross-correlation matching

Initial matches – motion vectors (188 pairs)

Global constraints

Robust estimation of the fundamental matrix (RANSAC)

99 inliers

89 outliers

Summary of the approach

- Very good results in the presence of occlusion and clutter
 - local information
 - discriminant greyvalue information
 - robust estimation of the global relation between images
 - works well for limited view point changes
- Solution for more general view point changes
 - wide baseline matching (different viewpoint, scale and rotation)
 - local invariant descriptors based on greyvalue information

Invariant Features

• Schmid & Mohr 1997, Lowe 1999, Baumberg 2000, Tuytelaars & Van Gool 2000, Mikolajczyk & Schmid 2001, Brown & Lowe 2002, Matas et. al. 2002, Schaffalitzky & Zisserman 2002

Approach

interest points

- 1) Extraction of interest points (characteristic locations)
- 2) Computation of local descriptors (rotational invariants)
- 3) Determining correspondences
- 4) Selection of similar images

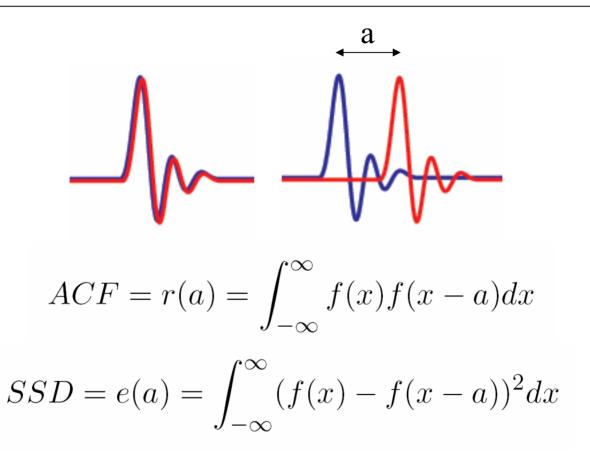

Based on the idea of auto-correlation

Important difference in all directions => interest point

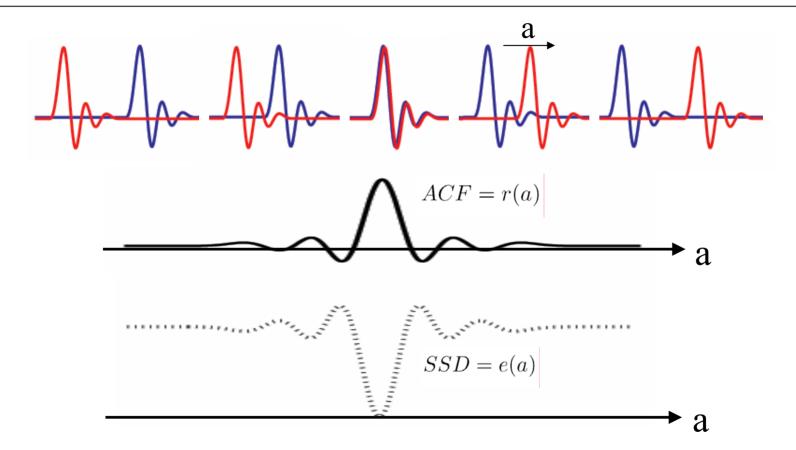

15

Autocorrelation

Autocorrelation function (ACF) measures the **self similarity** of a signal ₁₆

Autocorrelation

Autocorrelation related to sum-square difference:

$$SSD = 2(1 - ACF)$$

$$(if \int f(x)^2 dx = 1)$$

Background: Moravec Corner Detector

- take a window w in the image
- shift it in four directions (1,0), (0,1), (1,1), (-1,1)
- compute a difference for each
- compute the min difference at each pixel
- local maxima in the min image are the corners

$$\mathbf{E}(\mathbf{x},\mathbf{y}) = \sum_{\mathbf{u},\mathbf{v} \text{ in } \mathbf{w}} \mathbf{w}(\mathbf{u},\mathbf{v}) |\mathbf{I}(\mathbf{x}+\mathbf{u},\mathbf{y}+\mathbf{v}) - \mathbf{I}(\mathbf{u},\mathbf{v})|^2$$

Shortcomings of Moravec Operator

- Only tries 4 shifts. We'd like to consider "all" shifts.
- Uses a discrete rectangular window. We'd like to use a smooth circular (or later elliptical) window.
- Uses a simple min function. We'd like to characterize variation with respect to direction.

Result: Harris Operator

Auto-correlation fn (SSD) for a point (x, y) and a shift $(\Delta x, \Delta y)$

$$f(x, y) = \sum_{(x_k, y_k) \in W} (I(x_k, y_k) - I(x_k + \Delta x, y_k + \Delta y))^2$$

Discrete shifts can be avoided with the auto-correlation matrix

with
$$I(x_k + \Delta x, y_k + \Delta y) = I(x_k, y_k) + (I_x(x_k, y_k) - I_y(x_k, y_k)) \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix}$$

$$f(x,y) = \sum_{(x_k,y_k)\in W} \left(I_x(x_k,y_k) \quad I_y(x_k,y_k) \right) \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix}^2$$

Rewrite as inner (dot) product

$$f(x,y) = \sum_{(x_k,y_k)\in W} (\begin{bmatrix} I_x(x_k,y_k) & I_y(x_k,y_k) \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix})^2$$

$$= \sum_{(x_k,y_k)\in W} \begin{bmatrix} \Delta x & \Delta y \end{bmatrix} \begin{bmatrix} I_x(x_k,y_k) \\ I_y(x_k,y_k) \end{bmatrix} \begin{bmatrix} I_x(x_k,y_k) & I_y(x_k,y_k) \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}$$

The center portion is a 2x2 matrix

$$= \sum_{W} \begin{bmatrix} \Delta x & \Delta y \end{bmatrix} \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}$$
$$= \begin{bmatrix} \Delta x & \Delta y \end{bmatrix} \sum_{W} \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix}$$

$$= (\Delta x \quad \Delta y) \begin{bmatrix} \sum_{(x_k, y_k) \in W} (I_x(x_k, y_k))^2 & \sum_{(x_k, y_k) \in W} I_x(x_k, y_k) I_y(x_k, y_k) \\ \sum_{(x_k, y_k) \in W} (I_x(x_k, y_k)) I_y(x_k, y_k) & \sum_{(x_k, y_k) \in W} (I_y(x_k, y_k))^2 \end{bmatrix} (\Delta x)$$

Auto-correlation matrix M

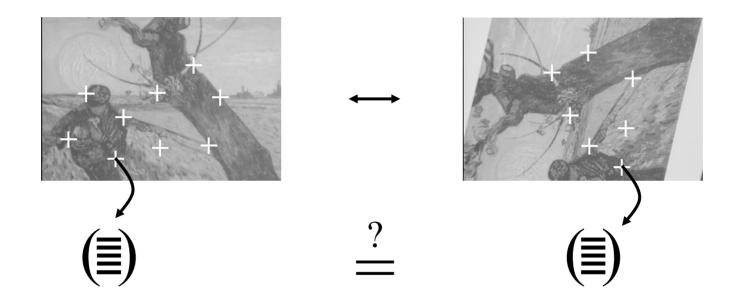

- Auto-correlation matrix
 - captures the structure of the local neighborhood
 - measure based on eigenvalues of M
 - 2 strong eigenvalues => interest point
 - 1 strong eigenvalue => contour
 - 0 eigenvalue => uniform region
- Interest point detection
 - threshold on the eigenvalues
 - local maximum for localization

Some Details from the Harris Paper

- Corner strength $R = Det(M) k Tr(M)^2$
- Let α and β be the two eigenvalues
- $Tr(M) = \alpha + \beta$
- $Det(M) = \alpha \beta$
- R is positive for corners, for edges, and small for flat regions
- Select corner pixels that are 8-way local maxima

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \qquad \det(\mathbf{A}) = a_{11}a_{22} - a_{12}a_{21} \\ \operatorname{tr}(\mathbf{A}) = a_{11} + a_{22}$$

Determining correspondences

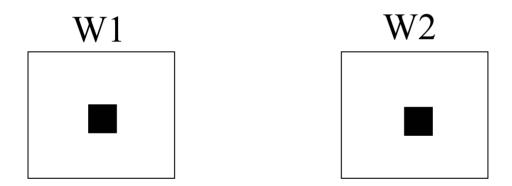

Vector comparison using a distance measure

What are some suitable distance measures?

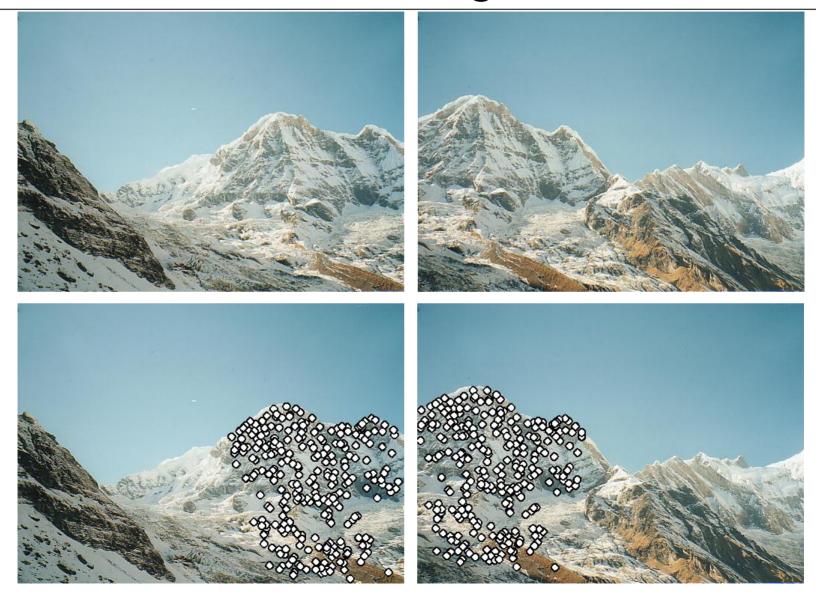

Distance Measures

 We can use the sum-square difference of the values of the pixels in a square neighborhood about the points being compared.

$$SSD = \sum \sum (W1(i,j) - (W2(i,j))^2$$

Some Matching Results

Some Matching Results

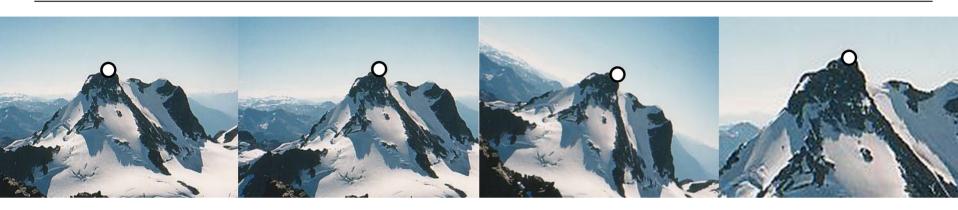

Summary of the approach

- Basic feature matching = Harris Corners & Correlation
- Very good results in the presence of occlusion and clutter
 - local information
 - discriminant greyvalue information
 - invariance to image rotation and illumination
- Not invariance to scale and affine changes
- Solution for more general view point changes
 - local invariant descriptors to scale and rotation
 - extraction of invariant points and regions

Invariant Features

 Local image descriptors that are invariant (unchanged) under image transformations

Canonical Frames

Canonical Frames

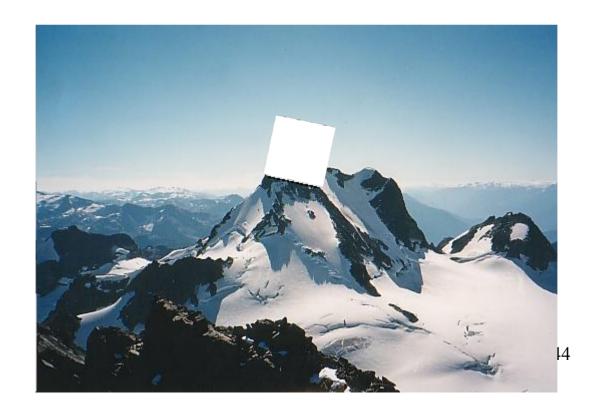

Extract oriented patches at multiple scales

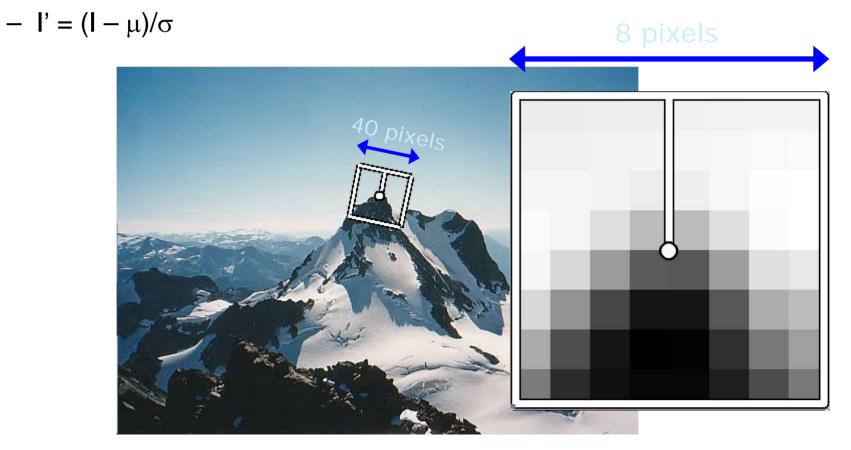

Sample scaled, oriented patch

- Sample scaled, oriented patch
 - 8x8 patch, sampled at 5 x scale

- Sample scaled, oriented patch
 - 8x8 patch, sampled at 5 x scale
- Bias/gain normalised

Matching Interest Points: Summary

- Harris corners / correlation
 - Extract and match repeatable image features
 - Robust to clutter and occlusion
 - BUT not invariant to scale and rotation
- Multi-Scale Oriented Patches
 - Corners detected at multiple scales
 - Descriptors oriented using local gradient
 - Also, sample a blurred image patch
 - Invariant to scale and rotation

Leads to: **SIFT** – state of the art image features
