“… data a new class of economic asset, like currency or gold.”
ML in the Context of Parallel Architectures

- But scalable ML in these systems is hard, especially in terms of:
  1. Programmability
  2. Data distribution
  3. Failures
Programmability Challenge 1: Designing Parallel programs

- SGD for LR:
  - For each data point $x^{(i)}$:
    $$ w_i^{(t+1)} \leftarrow w_i^{(t)} + \eta_t \left[ -\lambda w_i^{(t)} + \phi_i(x^{(t)})[y^{(t)} - P(Y = 1|\phi(x^{(t)}), w^{(t)})] \right] $$

  ![Diagram of SGD process](image)

  How do we parallelize?

Programmability Challenge 2: Race Conditions

- We are used to sequential programs:
  - Read data, think, write data, read data, think, write data, read data, think, write data, read data, think, write data, read data, think, write data, read data, think, write data...

- But, in parallel, you can have non-deterministic effects:
  - One machine reading data will other is writing

- Called a race-condition:
  - Very annoying
  - One of the hardest problems to debug in practice: because of non-determinism, bugs are hard to reproduce
Data Distribution Challenge

- Accessing data:
  - Main memory reference: 100ns ($10^{-7}$s)
  - Round trip time within data center: 500,000ns ($5 \times 10^{-4}$s)
  - Disk seek: 10,000,000ns ($10^{-2}$s)

- Reading 1MB sequentially:
  - Local memory: 250,000ns ($2.5 \times 10^{-4}$s)
  - Network: 10,000,000ns ($10^{-2}$s)
  - Disk: 30,000,000ns ($3 \times 10^{-2}$s)

- Conclusion: Reading data from local memory is much faster ➔ Must have data locality:
  - Good data partitioning strategy fundamental!
  - "Bring computation to data" (rather than moving data around)

Robustness to Failures Challenge

- From Google’s Jeff Dean, about their clusters of 1800 servers, in first year of operation:
  - 1,000 individual machine failures
  - thousands of hard drive failures
  - one power distribution unit will fail, bringing down 500 to 1,000 machines for about 6 hours
  - 20 racks will fail, each time causing 40 to 80 machines to vanish from the network
  - 5 racks will “go wonky,” with half their network packets missing in action
  - the cluster will have to be rewired once, affecting 5 percent of the machines at any given moment over a 2-day span
  - 50% chance cluster will overheat, taking down most of the servers in less than 5 minutes and taking 1 to 2 days to recover

- How do we design distributed algorithms and systems robust to failures?
  - It’s not enough to say: run, if there is a failure, do it again… because you may never finish
Move Towards Higher-Level Abstraction

- Distributed computing challenges are hard and annoying!
  1. Programmability
  2. Data distribution
  3. Failures
- High-level abstractions try to simplify distributed programming by hiding challenges:
  - Provide different levels of robustness to failures, optimizing data movement and communication, protect against race conditions…
  - Generally, you are still on your own WRT designing parallel algorithms

Some common parallel abstractions:
- Lower-level:
  - Pthreads: abstraction for distributed threads on single machine
  - MPI: abstraction for distributed communication in a cluster of computers
- Higher-level:
  - Map-Reduce (Hadoop: open-source version): mostly data-parallel problems
  - GraphLab: for graph-structured distributed problems

Simplest Type of Parallelism: Data Parallel Problems

- You have already learned a classifier
  - What’s the test error?
- You have 10B labeled documents and 1000 machines

- Problems that can be broken into independent subproblems are called data-parallel (or embarrassingly parallel)
- Map-Reduce is a great tool for this…
  - Focus of today’s lecture
  - but first a simple example
**Data Parallelism (MapReduce)**

*Solve a huge number of independent subproblems, e.g., extract features in images*

---

**Counting Words on a Single Processor**

- (This is the “Hello World!” of Map-Reduce)
- Suppose you have 10B documents and 1 machine
- You want to count the number of appearances of each word on this corpus
  - Similar ideas useful, e.g., for building Naive Bayes classifiers and computing TF-IDF
- Code:

  ```java
  Count[] int a hash table
  for d in document
    for word in d
      Count[word]++
  ```

©Carlos Guestrin 2013
Naïve Parallel Word Counting

- Simple data parallelism approach:

  - Merging hash tables: annoying, potentially not parallel ➔ no gain from parallelism???

Counting Words in Parallel & Merging Hash Tables in Parallel

- Generate pairs (word,count)
- Merge counts for each word in parallel
  - Thus parallel merging hash tables

Which words go to machines:

\[ h: X \rightarrow \{1, \ldots, \# machines\} \]

Send counts of word \( w \) to machine \( h(w) \)
Map-Reduce Abstraction

Map:
- Data-parallel over elements, e.g., documents
- Generate (key, value) pairs
  - "value" can be any data type

```
(String doc)
map(doc)
emit(doc, 1)
```

Reduce:
- Aggregate values for each key
- Must be commutative-associate operation
- Data-parallel over keys
- Generate (key, value) pairs

```
reduce (Word, count: List[Int])
c = 0
for i in count
  c += count[i]
emit (word, c)
```

Map-Reduce has long history in functional programming
- But popularized by Google, and subsequently by open-source Hadoop implementation from Yahoo!

Map Code (Hadoop): Word Count

```
public static class Map extends Mapper<LongWritable, Text, Text, IntWritable> {
    private final static IntWritable one = new IntWritable(1);
    private Text word = new Text();
    
    public void map(LongWritable key, Text value, Context context) throws <stuff> {
        String line = value.toString();
        StringTokenizer tokenizer = new StringTokenizer(line);
        while (tokenizer.hasMoreTokens()) {
            word.set(tokenizer.nextToken());
            context.write(word, one);
        }
    }
}
```
Reduce Code (Hadoop): Word Count

```java
public static class Reduce extendsReducer<Text, IntWritable, Text, IntWritable> {
    public void reduce(Text key, Iterable<IntWritable> values, Context context)
                   throws IOException, InterruptedException {
        int sum = 0;
        for (IntWritable val : values) {
            sum += val.get();
        }
        context.write(key, new IntWritable(sum));
    }
}
```

Map-Reduce Parallel Execution

©Carlos Guestrin 2013
Map-Reduce – Execution Overview

Map Phase | Shuffle Phase | Reduce Phase
---|---|---

Split data across machines

Assign tuple \((k, v)\) to machine \(h[k]\)

Map-Reduce – Robustness to Failures 1: Protecting Data: **Save To Disk Constantly**

Split data across machines

Assign tuple \((k, v)\) to machine \(h[k]\)
Distributed File Systems

- Saving to disk locally is not enough → If disk or machine fails, all data is lost
- Replicate data among multiple machines!

**Distributed File System (DFS)**
- Write a file anywhere → automatically replicated
- Can read a file anywhere → read from closest copy
  - If failure, try next closest copy

**Important practical considerations:**
- Write large files
  - Many small files → becomes way too slow
- Typically, files can’t be “modified”, just “replaced” → makes robustness much simpler

Map-Reduce – Robustness to Failures 2: Recovering From Failures: **Read from DFS**

- Communication in initial distribution & shuffle phase “automatic”
  - Done by DFS
- If failure, don’t restart everything
  - Otherwise, never finish
- Only restart Map/Reduce jobs in dead machines
Improving Performance: Combiners

- Naïve implementation of M-R very wasteful in communication during shuffle:

  ![Diagram of data flow and communication]

  - **Combiner**: Simple solution, perform reduce locally before communicating for global reduce
    - Works because reduce is commutative-associative

(A few of the) Limitations of Map-Reduce

- Too much synchrony
  - E.g., reducers don’t start until all mappers are done
- “Too much” robustness
  - Writing to disk all the time
- Not all problems fit in Map-Reduce
  - E.g., you can’t communicate between mappers
- Oblivious to structure in data
  - E.g., if data is a graph, can be much more efficient
    - For example, no need to shuffle nearly as much
- Nonetheless, extremely useful; industry standard for Big Data
  - Though many many companies are moving away from Map-Reduce (Hadoop)
What you need to know about Map-Reduce

- Distributed computing challenges are hard and annoying!
  1. Programmability
  2. Data distribution
  3. Failures

- High-level abstractions help a lot!

- Data-parallel problems & Map-Reduce

- Map:
  - Data-parallel transformation of data
    - Parallel over data points

- Reduce:
  - Data-parallel aggregation of data
    - Parallel over keys

- Combiner helps reduce communication

- Distributed execution of Map-Reduce:
  - Map, shuffle, reduce
  - Robustness to failure by writing to disk
  - Distributed File Systems

Case Study 2: Document Retrieval
K-means

1. Ask user how many clusters they'd like. *(e.g. k=5)*
K-means

1. Ask user how many clusters they'd like. 
   (e.g. $k=5$)
2. Randomly guess $k$ cluster Center locations
3. Each datapoint finds out which Center it's closest to. (Thus each Center "owns" a set of datapoints)
1. Ask user how many clusters they’d like. *(e.g. k=5)*
2. Randomly guess k cluster Center locations.
3. Each datapoint finds out which Center it’s closest to.
4. Each Center finds the centroid of the points it owns…
5. …and jumps there.
6. …Repeat until terminated!

©2005-2009 Carlos Guestrin
K-means

- Randomly initialize $k$ centers
  - $\mu^{(0)} = \mu_1^{(0)}, \ldots, \mu_k^{(0)}$

- **Classify**: Assign each point $j \in \{1, \ldots, m\}$ to nearest center:
  - $z^j \leftarrow \arg \min_i ||\mu_i - x^j||_2$

- **Recenter**: $\mu_i$ becomes centroid of its point:
  - $\mu_i^{(t+1)} \leftarrow \arg \min_\mu \sum_{j: z^j = i} ||\mu - x^j||_2$
  - Equivalent to $\mu_i \leftarrow$ average of its points!

Special case: spherical Gaussians

Mixtures and hard assignments

\[ P(z = i | x^j) \propto \frac{1}{(2\pi)^{m/2} \left| \Sigma_i \right|^{1/2}} \exp \left[ -\frac{1}{2} (x^j - \mu_i)^T \Sigma_i^{-1} (x^j - \mu_i) \right] P(z = i) \]

- If $P(Z|i|X)$ is spherical, with same $\sigma$ for all classes:
  \[ P(z = i | x^j) \propto \exp \left[ -\frac{1}{2 \sigma^2} \|x^j - \mu_i\|^2 \right] \]
  - "Expectation": $z^j \in \{ 1, \ldots, k \}$
  - "Assignment": $z^j \in \{ 1, \ldots, k \}$

- If each $x^j$ belongs to one class $z^j$ (hard assignment), marginal likelihood:
  \[ \prod_{j=1}^m \sum_{i=1}^k P(x^j, z = i) \propto \prod_{j=1}^m \exp \left[ -\frac{1}{2 \sigma^2} \|x^j - \mu_i\|^2 \right] = \frac{1}{(2\pi)^{m/2}} \frac{1}{\left| \Sigma_i \right|^{1/2}} \exp \left[ -\frac{1}{2 \sigma^2} \|x^j - \mu_i\|^2 \right] \]

- Same as K-means!!!

\[ \text{if only solve for } \mu \]
Map-Reducing One Iteration of K-Means

- **Classify**: Assign each point \( j \in \{1, \ldots, m\} \) to nearest center:
  \[ z_j^{\ell} \leftarrow \arg\min_i \|\mu_i - x_j^{\ell}\|_2^2 \]

- **Recenter**: \( \mu_\ell \) becomes centroid of its point:
  \[ \mu_{i}^{(\ell+1)} \leftarrow \arg\min \ell \sum_{j: z_j^{\ell}=i} \|\mu - x_j^{\ell}\|_2^2 \]
  Equivalent to \( \mu_\ell \leftarrow \text{average of its points!} \)

- **Map**: data-parallel: classify phase
  for each data point : given \((\mu_\ell, \mathbf{x})\) →

- **Reduce**: recenter phase: average over all points in class \( i \)

Classification Step as Map

- **Classify**: Assign each point \( j \in \{1, \ldots, m\} \) to nearest center:
  \[ z_j^{\ell} \leftarrow \arg\min_i \|\mu_i - x_j^{\ell}\|_2^2 \]

- **Map**:
  \[ \text{map } ([\mu_1, \ldots, \mu_k], x^{\ell}) \]
  \[ z_j^{\ell} \leftarrow \arg\min_i \|\mu_i - x_j^{\ell}\|_2^2 \]
  \[ \text{emit } (z_j^{\ell}, x_j^{\ell}) \]
  \[ \sqrt{z_j^{\ell}} = 2 \]
  \[ \text{emit } (z_j^{\ell}, (1, 1, 17, \text{op}, 1, 7, 2)) \]
  \[ \text{reduce } \]
Recenter Step as Reduce

- **Recenter:** $\mu_i$ becomes centroid of its point:
  - $\mu_i^{(t+1)} \leftarrow \arg \min_{\mu} \sum_{j:z^t_j=i} ||\mu - x^j||^2_2$
  - Equivalent to $\mu_i \leftarrow \text{average of its points!}$

- **Reduce:**
  - $\text{reduce}(i, \text{list}\cdot x: [x^1, x^2, \ldots])$
    
    ```python
    count = 0
    sum = 0
    for x in list\cdot x:
        sum += x
        count += 1
    limit(i, sum / count)
    ```

Some Practical Considerations

- **K-Means needs an iterative version of Map-Reduce**
  - Not standard formulation

- **Mapper needs to get data point and all centers**
  - A lot of data!
  - Better implementation: mapper gets many data points
What you need to know about Parallel K-Means on Map-Reduce

- K-Means = EM for mixtures of spherical Gaussians with hard assignments

- Map: classification step; data parallel over data point

- Reduce: recompute means; data parallel over centers
