Case study: Snowflake

Snowflake

- It is an SaaS – what is this? Give other examples of types of cloud services...

Snowflake

- It is an SaaS – what is this? Give other examples of types of cloud services...
- SaaS = software as a service
- Other examples:
 - Platform as a service (PaaS): e.g. Amazon's EC
 - Infrastructure as a service (virtual machines)
 - Function as a Service: Amazon's Lambda

Snowflake

- Describe Snowflake's Data Storage

Snowflake

- Describe Snowflake's Data Storage

In class:

- S3:PUT/GET/DELETE
- Table → horizontal partition in files
- Blobs+PAX
- Temp storage → S3

Figure 1: Multi-Cluster, Shared Data Architecture

Snowflake

- Describe Elasticity in Snowflake
- Describe failure handling in Snowflake

Snowflake

- Describe Elasticity in Snowflake
 - Virtual Warehouse (VW) serves one user
 - T-Shirt sizes: X-Small ... XX-Large
 - Small query may run on subset of VW
- Describe failure handling in Snowflake

Snowflake

- Describe Elasticity in Snowflake
 - Virtual Warehouse (VW) serves one user
 - T-Shirt sizes: X-Small ... XX-Large
 - Small query may run on subset of VW
- Describe failure handling in Snowflake
 - Restart the query
 - No partial retries (like MapReduce or Spark)

Snowflake

- Describe its execution engine

Snowflake

- Describe its execution engine
 - Column-oriented (in class)
 - Vectorized (in class)
 - Push-based (in class)

Snowflake

- What does Snowflake use instead of indexes?

Snowflake

- What does Snowflake use instead of indexes?
 - “Pruning”: for each file (recall: this is a horizontal partition of a table) and each attribute, it stores the min/max values in that column in that file; may skip files when not needed.

Outline

- Recap: Datalog basics
- Naïve Evaluation Algorithm
- Monotone Queries
- Non-monotone Extensions

Datalog program

- A datalog program = several rules
- Rules may be recursive
- Set semantics only

Naïve Evaluation Algorithm

The Naïve Evaluation Algorithm:

- Always terminates
- Always terminates in a number of steps that is polynomial in the size of the database

Before we show this, a digression: **monotone queries**

Outline

- Recap: Datalog basics
- Naïve Evaluation Algorithm
- Monotone Queries
- Non-monotone Extensions

Review: Monotone Functions

- A function $f(x)$ is called monotonically increasing, or just monotone if:

If $x \leq y$ then $f(x) \leq f(y)$

Monotone Queries

- A query with input relations R, S, T, \dots is called monotone if, whenever we increase a relation, the query answer also increases (or stays the same)
- Increase here means larger set

Monotone Queries

- A query with input relations R, S, T, \dots is called monotone if, whenever we increase a relation, the query answer also increases (or stays the same)
- Increase here means larger set
- Mathematically

If $R \subseteq R', S \subseteq S', \dots$ then $Q(R, S, \dots) \subseteq Q(R', S', \dots)$

Fun Fact

- A SELECT-FROM-WHERE query (without aggregates or subqueries) is monotone

```
SELECT [DISTINCT] ...  
FROM R1 x1, R2 x2, ...  
WHERE ...
```

Fun Fact

- A **SELECT-FROM-WHERE** query (without aggregates or subqueries) is monotone

```
SELECT [DISTINCT] ...  
FROM R1 x1, R2 x2, ...  
WHERE ...
```

- **Proof: the nested loop semantics!**
When we add tuples to one relation, we cannot lose answers:

```
for x1 in R1 do:  
  for x2 in R2 do:  
    ...
```

Tips for Writing SQL Queries

- If the English formulation of a query is non-monotone, then you need to use a subquery OR aggregate in SQL

Return SUPPLIERS who supply
some product with price > \$10000

Return SUPPLIERS who supply
only products with price > \$10000

Back to Datalog

Naïve Algorithm:

- Always terminates
- Terminates in a number of steps that is polynomial in the size of the database
- This is cool!
Compare with java, python, etc

Assumptions:

- Set semantics only
- Monotone rules only
- No “value invention”

Will show this next

Naïve Evaluation Algorithm

Consequence: The naïve algorithm terminates, in $O(n^k)$ steps, where:

- n = number of distinct values in the DB
- k = arity of widest IDB relation

Proof: IDBs increases to $\leq O(n^k)$ facts

Non-monotone Extensions

- Aggregates
 - Grouping
 - Negation
- No standard syntax
We will follow Souffle

Actor(id, fname, lname)

Casts(pid, mid)

Movie(id, name, year)

Aggregates

$Q(m) :- m = \text{min } x : \{ \text{Actor}(x, y, _), y = \text{'John'} \}$

Actor(id, fname, lname)

Casts(pid, mid)

Movie(id, name, year)

Aggregates

$Q(m) :- m = \min x : \{ \text{Actor}(x, y, _), y = \text{'John'} \}$

Meaning (in SQL)

```
SELECT min(id) as m
FROM Actor as a

```

Problem: this includes answers like SG(Carol, Carol)

And also SG(Eve, George), SG(George, Eve)

How to fix?

ParentChild(p,c)

Same Generation

Compute pairs of people at the same generation

```
// common parent
```

```
SG(x,y) :- ParentChild(p,x), ParentChild(p,y),  $x < y$ 
```

```
// parents at the same generation

SG(x,y) :- ParentChild(p,x), ParentChild(q,y),  
           SG(p,q),  $x < y$ 
```

Stratified Datalog

Recursion conflicts with non-monotone queries

- Example: what does this mean?

```
Happy(Bob):- !Happy(Alice).  
Happy(Alice) :- !Happy(Bob).
```

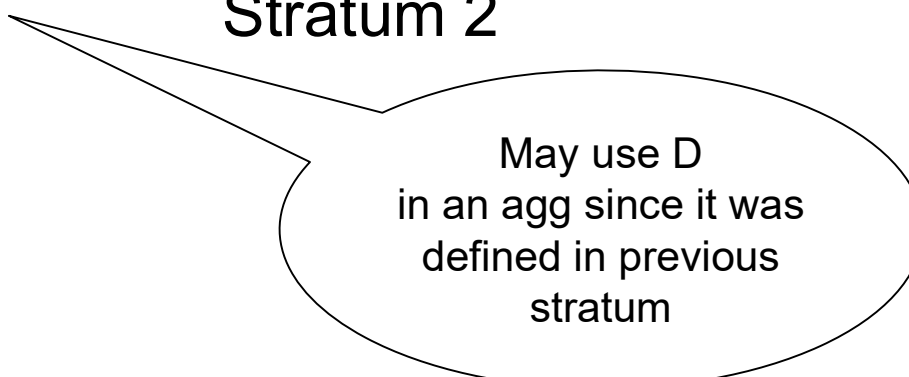

- A program is *stratified* if it can be partitioned into *strata*, such that every IDB predicate in a non-monotone position has been defined in an earlier stratum

Stratified Datalog

D(x,y) :- ParentChild(x,y).
D(x,z) :- D(x,y), ParentChild(y,z).
T(p,c) :- D(p,_), c = count : { D(p,_) }.
Q(d) :- T(p,d), p = "Alice".

Stratum 1

Stratum 2

May use D
in an agg since it was
defined in previous
stratum

Summary

- Datalog = light-weight syntax, recursion
- Data independence
- Limitations:
 - Monotone queries work great
 - Non-monotone queries: various restrictions
