

CSE P 501 – Compilers

LR Parsing
Hal Perkins
Summer 2004

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-1

Agenda

- LR Parsing
- Table-driven Parsers
- Parser States
- Shift-Reduce and Reduce-Reduce conflicts

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-2

LR(1) Parsing

- We'll look at LR(1) parsers
 - Left to right scan, Rightmost derivation, 1 symbol lookahead
 - Almost all practical programming languages have an LR(1) grammar
 - LALR(1), SLR(1), etc. – subsets of LR(1)
 - LALR(1) can parse most real languages, is more compact, and is used by YACC/Bison/etc.

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-3

Bottom-Up Parsing

- Idea: Read the input left to right
- Whenever we've matched the right hand side of a production, reduce it to the appropriate non-terminal and add that non-terminal to the parse tree
- The upper edge of this partial parse tree is known as the *frontier*

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-4

Example

- Grammar
- Bottom-up Parse

$S ::= aABe$
 $A ::= Abc \mid b$
 $B ::= d$

a b b c d e

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-5

Details

- The bottom-up parser reconstructs a reverse rightmost derivation
- Given the rightmost derivation $S \Rightarrow \beta_1 \Rightarrow \beta_2 \Rightarrow \dots \Rightarrow \beta_{n-2} \Rightarrow \beta_{n-1} \Rightarrow \beta_n = w$ the parser will first discover $\beta_{n-1} \Rightarrow \beta_n$, then $\beta_{n-2} \Rightarrow \beta_{n-1}$, etc.
- Parsing terminates when
 - β_1 reduced to S (start symbol, success), or
 - No match can be found (syntax error)

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-6

How Do We Parse with This?

- Key: given what we've already seen and the next input symbol, decide what to do.
- Choices:
 - Perform a reduction
 - Look ahead further
- Can reduce $A \Rightarrow \beta$ if both of these hold:
 - $A \Rightarrow \beta$ is a valid production
 - $A \Rightarrow \beta$ is a step in *this* rightmost derivation
- This is known as a *shift-reduce* parser

D-7

Sentential Forms

- If $S \Rightarrow^* \alpha$, the string α is called a *sentential form* of the grammar
- In the derivation $S \Rightarrow \beta_1 \Rightarrow \beta_2 \Rightarrow \dots \Rightarrow \beta_{n-2} \Rightarrow \beta_{n-1} \Rightarrow \beta_n = w$ each of the β_j are sentential forms
- A sentential form in a rightmost derivation is called a *right-sentential form* (similarly for leftmost and left-sentential)

6/29/2004

D-8

Handles

- Informally, a substring of the tree frontier that matches the right side of a production
 - Even if $A ::= \beta$ is a production, β is a handle only if it matches the frontier at a point where $A ::= \beta$ was used in the derivation
 - β may appear in many other places in the frontier without being a handle for that production

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-9

Handles (cont.)

- Formally, a *handle* of a right-sentential form γ is a production $A ::= \beta$ and a position in γ where β may be replaced by A to produce the previous right-sentential form in the rightmost derivation of γ

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-10

Handle Examples

- In the derivation $S \Rightarrow aAbc \Rightarrow aAde \Rightarrow aAbcde \Rightarrow abcde$
 - $abcde$ is a right sentential form whose handle is $A ::= b$ at position 2
 - $aAbcde$ is a right sentential form whose handle is $A ::= abc$ at position 4
 - Note: some books take the left of the match as the position (e.g., Dragon Book)

D-11

Implementing Shift-Reduce Parsers

- Key Data structures
 - A stack holding the frontier of the tree
 - A string with the remaining input

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-12

Shift-Reduce Parser Operations

- *Reduce* – if the top of the stack is the right side of a handle $A ::= \beta$, pop the right side β and push the left side A .
- *Shift* – push the next input symbol onto the stack
- *Accept* – announce success
- *Error* – syntax error discovered

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-13

Shift-Reduce Example

$S ::= aABe$
 $A ::= Abc \mid b$
 $B ::= d$

Stack	Input	Action
\$	abcde\$	<i>shift</i>

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-14

How Do We Automate This?

- Def. *Viable prefix* – a prefix of a right-sentential form that can appear on the stack of the shift-reduce parser
 - Equivalent: a prefix of a right-sentential form that does not continue past the rightmost handle of that sentential form
- Idea: Construct a DFA to recognize viable prefixes given the stack and remaining input
 - Perform reductions when we recognize them

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-15

DFA for prefixes of

$S ::= aABe$
 $A ::= Abc \mid b$
 $B ::= d$

6/29/2004

D-17

Observations

- Way too much backtracking
 - We want the parser to run in time proportional to the length of the input
- Where the heck did this DFA come from anyway?
 - From the underlying grammar
 - We'll defer construction details for now

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-18

Avoiding DFA Rescanning

- Observation: after a reduction, the contents of the stack are the same as before except for the new non-terminal on top
 - ∴ Scanning the stack will take us through the same transitions as before until the last one
 - ∴ If we record state numbers on the stack, we can go directly to the appropriate state when we pop the right hand side of a production from the stack

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-19

Stack

- Change the stack to contain pairs of states and symbols from the grammar
$$s_0 X_1 S_1 X_1 S_1 \dots X_n S_n$$
 - State s_0 represents the accept state
 - (Not always added – depends on particular presentation)
- Observation: in an actual parser, only the state numbers need to be pushed, since they implicitly contain the symbol information, but for explanations, it's clearer to use both.

6/29/2004

D-20

Encoding the DFA in a Table

- A shift-reduce parser's DFA can be encoded in two tables
 - One row for each state
 - *action* table encodes what to do given the current state and the next input symbol
 - *goto* table encodes the transitions to take after a reduction

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-21

Actions (1)

- Given the current state and input symbol, the main possible actions are
 - *si* – shift the input symbol and state *i* onto the stack (i.e., shift and move to state *i*)
 - *rj* – reduce using grammar production *j*
 - The production number tells us how many <symbol, state> pairs to pop off the stack

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-22

Actions (2)

- Other possible *action* table entries
 - *accept*
 - blank – no transition – syntax error
 - A LR parser will detect an error as soon as possible on a left-to-right scan
 - A real compiler needs to produce an error message, recover, and continue parsing when this happens

6/29/2004

© 2002-04 Hal Perkins & UW CSE

D-23

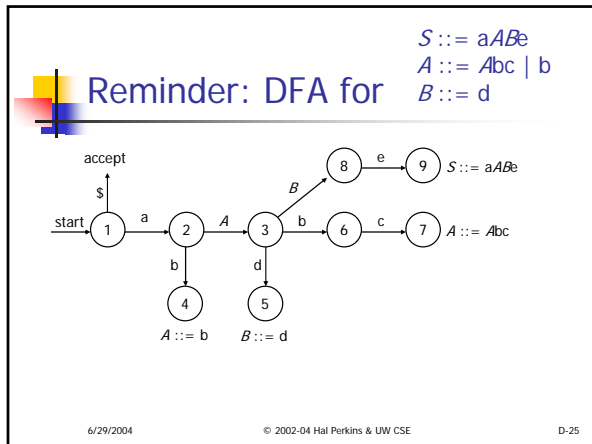

Goto

- When a reduction is performed, <symbol, state> pairs are popped from the stack revealing a state *uncovered_s* on the top of the stack
- *goto*[*uncovered_s*, *A*] is the new state to push on the stack when reducing production $A ::= \beta$ (after popping β)

D-24

LR Parse Table for

① $S ::= aAB\epsilon$
 ② $A ::= Abc$
 ③ $A ::= b$
 ④ $B ::= d$

State	action						goto	
	a	b	c	d	e	\$	A	B
1	s2					acc		
2		s4					g3	
3		s6		s5				g8
4	r3	r3	r3	r3	r3	r3		
5	r4	r4	r4	r4	r4	r4		
6			s7					
7	r2	r2	r2	r2	r2	r2		
8					s9			
9	r1	r1	r1	r1	r1	r1		

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-26

LR Parsing Algorithm (1)

```

word = scanner.getToken();
while (true) {
    s = top of stack;
    if (action[s, word] = s1) {
        push word; push i (state);
        word = scanner.getToken();
    } else if (action[s, word] = r1) {
        pop 2 * length of right side of
        production j (2*|β|);
        uncovered_s = top of stack;
        push left side A of production j;
        push state goto[uncovered_s, A];
    } else if (action[s, word] = accept) {
        return;
    } else {
        // no entry in action table
        report syntax error;
        halt or attempt recovery;
    }
}

```

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-27

Example

① $S ::= aAB\epsilon$
 ② $A ::= Abc$
 ③ $A ::= b$
 ④ $B ::= d$

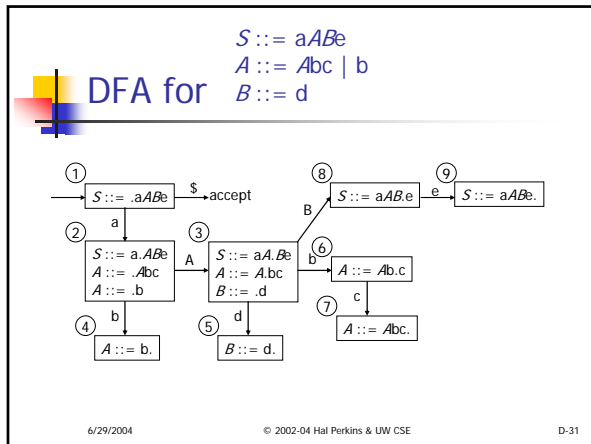

Stack: \$ Input: abbcde\$

s	action						goto	
	a	b	c	d	e	\$	A	B
1	s2					ac		
2		s4					g3	
3		s6		s5				g8
4	r3	r3	r3	r3	r3	r3		
5	r4	r4	r4	r4	r4	r4		
6			s7					
7	r2	r2	r2	r2	r2	r2		
8					s9			
9	r1	r1	r1	r1	r1	r1		

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-28

- ### LR States
- Idea is that each state encodes
 - The set of all possible productions that we could be looking at, given the current state of the parse, and
 - Where we are in the right hand side of each of those productions
- 6/29/2004 © 2002-04 Hal Perkins & UW CSE D-29

- ### Items
- An *item* is a production with a dot in the right hand side
 - Example: Items for production $A ::= XY$
 - $A ::= .XY$
 - $A ::= X.Y$
 - $A ::= XY.$
 - Idea: The dot represents a position in the production
- 6/29/2004 © 2002-04 Hal Perkins & UW CSE D-30

Problems with Grammars

- Grammars can cause to problems when constructing a LR parser
 - Shift-reduce conflicts
 - Reduce-reduce conflicts

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-32

Shift-Reduce Conflicts

- Situation: both a shift and a reduce are possible at a given point in the parse (equivalently: in a particular state of the DFA)
- Classic example: if-else statement

$$S ::= \text{ifthen } S \mid \text{ifthen } S \text{ else } S$$

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-33

Parser States for

① $S ::= \text{ifthen } S$
 ② $S ::= \text{ifthen } S \text{ else } S$

- State 3 has a shift-reduce conflict
 - Can shift past else into state 4 (s4)
 - Can reduce (r1) $S ::= \text{ifthen } S$

(Note: other $S ::= \text{ifthen } S$ items not included in states 2-4 to save space)

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-34

Solving Shift-Reduce Conflicts

- Fix the grammar
 - Done in Java reference grammar, others
- Use a parse tool with a "longest match" rule – i.e., if there is a conflict, choose to shift instead of reduce
 - Does exactly what we want for if-else case
 - Guideline: a few shift-reduce conflicts are fine, but be sure they do what you want

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-35

Reduce-Reduce Conflicts

- Situation: two different reductions are possible in a given state
- Contrived example

$$S ::= A$$

$$S ::= B$$

$$A ::= x$$

$$B ::= x$$

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-36

Parser States for

① $S ::= A$
 ② $S ::= B$
 ③ $A ::= x$
 ④ $B ::= x$

① $S ::= \cdot A$
 $S ::= \cdot B$
 $A ::= \cdot x$
 $B ::= \cdot x$

$\downarrow x$
 ② $A ::= x \cdot$
 $B ::= x \cdot$

- State 2 has a reduce-reduce conflict (r3, r4)

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-37

Handling Reduce-Reduce Conflicts

- These normally indicate a serious problem with the grammar.
- Fixes
 - Use a different kind of parser generator that takes lookahead information into account when constructing the states (LR(1) instead of SLR(1) for example)
 - Most practical tools already use this information
 - Fix the grammar

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-38

Another Reduce-Reduce Conflict

- Suppose the grammar separates arithmetic and boolean expressions

```

            expr ::= aexp | bexp
            aexp ::= aexp * aident | aident
            bexp ::= bexp && bident | bident
            aident ::= id
            bident ::= id
            
```
- This will create a reduce-reduce conflict

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-39

Covering Grammars

- A solution is to merge *aident* and *bident* into a single non-terminal (or use *id* in place of *aident* and *bident* everywhere they appear)
- This is a *covering grammar*
 - Includes some programs that are not generated by the original grammar
 - Use the type checker or other static semantic analysis to weed out illegal programs later

6/29/2004 © 2002-04 Hal Perkins & UW CSE D-40

Coming Attractions

- Constructing LR tables
 - We'll present a simple version (SLR(0)) in lecture, then talk about extending it to LR(1)
- LL parsers and recursive descent
- Continue reading ch. 3
