Agenda

- Basic concepts of formal grammars (review)
- Regular expressions
- Lexical specification of programming languages
- Using finite automata to recognize regular expressions
- Scanners and Tokens
Programming Language Specs

- Since the 1960s, the syntax of every significant programming language has been specified by a formal grammar
  - First done in 1959 with BNF (Backus-Naur Form or Backus-Normal Form) used to specify the syntax of ALGOL 60
  - Borrowed from the linguistics community (Chomsky)
Grammar for a Tiny Language

- `program ::= statement | program statement`
- `statement ::= assignStmt | ifStmt`
  - `assignStmt ::= id = expr ;`
  - `ifStmt ::= if ( expr ) stmt`
- `expr ::= id | int | expr + expr`
- `id ::= a | b | c | i | j | k | n | x | y | z`
- `int ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9`
Productions

- The rules of a grammar are called *productions*.
- Rules contain:
  - Nonterminal symbols: grammar variables (*program*, *statement*, *id*, etc.)
  - Terminal symbols: concrete syntax that appears in programs (*a*, *b*, *c*, *0*, *1*, *if*, *( ), ... *)
- Meaning of:
  
  \[ \text{nonterminal} ::= \text{<sequence of terminals and nonterminals>} \]
  
  In a derivation, an instance of *nonterminal* can be replaced by the sequence of terminals and nonterminals on the right of the production.
- Often, there are two or more productions for one nonterminal – use any in different parts of derivation.
Alternative Notations

- There are several syntax notations for productions in common use; all mean the same thing

  $ifStmt ::= if ( expr ) stmt$

  $\underline{ifStmt} \rightarrow if ( expr ) stmt$

  $<ifStmt> ::= if ( <expr> ) <stmt>$
Example Derivation

```
program ::= statement | program statement
statement ::= assignStmt | ifStmt
assignStmt ::= id = expr ;
ifStmt ::= if ( expr ) stmt
expr ::= id | int | expr + expr
id ::= a | b | c | i | j | k | n | x | y | z
int ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
```

\[ \rightarrow \quad a = 1 ; \text{ if ( } a + 1 \text{ ) } b = 2 ; \]
Parsing

- Parsing: reconstruct the derivation (syntactic structure) of a program
- In principle, a single recognizer could work directly from a concrete, character-by-character grammar
- In practice this is never done
Parsing & Scanning

- In real compilers the recognizer is split into two phases
  - Scanner: translate input characters to tokens
    - Also, report lexical errors like illegal characters and illegal symbols
  - Parser: read token stream and reconstruct the derivation

10/6/2009 © 2002-09 Hal Perkins & UW CSE
Characters vs Tokens (review)

- **Input text**
  ```
  // this statement does very little
  if (x >= y) y = 42;
  ```

- **Token Stream**
  ```
  IF LPAREN ID(x) GEQ ID(y) RPAREN ID(y) BECOMES INT(42) SCOLON
  ```
Why Separate the Scanner and Parser?

- Simplicity & Separation of Concerns
  - Scanner hides details from parser (comments, whitespace, input files, etc.)
  - Parser is easier to build; has simpler input stream (tokens)

- Efficiency
  - Scanner can use simpler, faster design
    (But still often consumes a surprising amount of the compiler’s total execution time)
Tokens

- Idea: we want a distinct token kind (lexical class) for each distinct terminal symbol in the programming language
  - Examine the grammar to find these

- Some tokens may have attributes
  - Examples: integer constant token will have the actual integer (17, 42, ...) as an attribute; identifiers will have a string with the actual id
Typical Tokens in Programming Languages

- Operators & Punctuation
  - `+` `-` `*` `/` `( )` `{ }` `[]` `;` `::` `<` `<=` `==` `!=` `!` ...
  - Each of these is normally a distinct lexical class

- Keywords
  - `if` `while` `for` `goto` `return` `switch` `void` ...
  - Each of these is also a distinct lexical class (*not* a string)

- Identifiers
  - A single ID lexical class, but parameterized by actual id

- Integer constants
  - A single INT lexical class, but parameterized by int value

- Other constants, etc.
Principle of Longest Match

- In most languages, the scanner should pick the longest possible string to make up the next token if there is a choice.

- Example:

  ```
  return maybe != iffy;
  ```

  should be recognized as 5 tokens:

  ```
  RETURN ID(maybe) NEQ ID(iffy) SCOLON
  ```

  i.e., `!=` is one token, not two, “iffy” is an ID, not IF followed by ID(fy)
Formal Languages & Automata Theory (a review in one slide)

- Alphabet: a finite set of symbols
- String: a finite, possibly empty sequence of symbols from an alphabet
- Language: a set, often infinite, of strings
- Finite specifications of (possibly infinite) languages
  - Automaton – a recognizer; a machine that accepts all strings in a language (and rejects all other strings)
  - Grammar – a generator; a system for producing all strings in the language (and no other strings)

- A particular language may be specified by many different grammars and automata
- A grammar or automaton specifies only one language
Regular Expressions and FAs

- The lexical grammar (structure) of most programming languages can be specified with regular expressions
  - (Sometimes a little cheating is needed)
- Tokens can be recognized by a deterministic finite automaton
  - Can be either table-driven or built by hand based on lexical grammar
Regular Expressions

- Defined over some alphabet $\Sigma$
  - For programming languages, alphabet is usually ASCII or Unicode
- If $re$ is a regular expression, $L(re)$ is the language (set of strings) generated by $re$
### Fundamental REs

<table>
<thead>
<tr>
<th>$re$</th>
<th>$L(re)$</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>$a$</td>
<td>${ a }$</td>
<td>Singleton set, for each $a$ in $\Sigma$</td>
</tr>
<tr>
<td>$\varepsilon$</td>
<td>${ \varepsilon }$</td>
<td>Empty string</td>
</tr>
<tr>
<td>$\emptyset$</td>
<td>${ }$</td>
<td>Empty language</td>
</tr>
</tbody>
</table>
## Operations on REs

<table>
<thead>
<tr>
<th>re</th>
<th>$L(re)$</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>$rs$</td>
<td>$L(r)L(s)$</td>
<td>Concatenation</td>
</tr>
<tr>
<td>$r</td>
<td>s$</td>
<td>$L(r) \cup L(s)$</td>
</tr>
<tr>
<td>$r^*$</td>
<td>$L(r)^*$</td>
<td>0 or more occurrences (Kleene closure)</td>
</tr>
</tbody>
</table>

- Precedence: $^*$ (highest), concatenation, $|$ (lowest)
- Parentheses can be used to group REs as needed
## Abbreviations

- The basic operations generate all possible regular expressions, but there are common abbreviations used for convenience. Typical examples:

<table>
<thead>
<tr>
<th>Abbr.</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>r+</td>
<td>(rr*)</td>
<td>1 or more occurrences</td>
</tr>
<tr>
<td>r?</td>
<td>(r</td>
<td>ε)</td>
</tr>
<tr>
<td>[a-z]</td>
<td>(a</td>
<td>b</td>
</tr>
<tr>
<td>[abxyz]</td>
<td>(a</td>
<td>b</td>
</tr>
</tbody>
</table>
# Examples

<table>
<thead>
<tr>
<th>re</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>single + character</td>
</tr>
<tr>
<td>!</td>
<td>single ! character</td>
</tr>
<tr>
<td>=</td>
<td>single = character</td>
</tr>
<tr>
<td>!=</td>
<td>2 character sequence</td>
</tr>
<tr>
<td>&lt;=</td>
<td>2 character sequence</td>
</tr>
<tr>
<td>xyzzy</td>
<td>5 character sequence</td>
</tr>
</tbody>
</table>
## More Examples

<table>
<thead>
<tr>
<th>re</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>[abc]+</td>
<td>a b c  c ab a c b  a b c abc abc abc abc abc</td>
</tr>
<tr>
<td>[abc]*</td>
<td>above or ε</td>
</tr>
<tr>
<td>[0-9]+</td>
<td>1 or more digits</td>
</tr>
<tr>
<td>[1-9][0-9]*</td>
<td>1 or more digits, no leading 0</td>
</tr>
<tr>
<td>[a-zA-Z][a-zA-Z0-9_]*</td>
<td>lol</td>
</tr>
</tbody>
</table>
Abbreviations

- Many systems allow abbreviations to make writing and reading definitions or specifications easier

\[
\text{name ::= } \text{re} \\
\text{digits ::= } [0-9]^* \\
\]

- Restriction: abbreviations may not be circular (recursive) either directly or indirectly (else would be non-regular)
Example

Possible syntax for numeric constants

\[ \text{digit ::= [0-9]} \]
\[ \text{digits ::= digit}^+ \]
\[ \text{number ::= digits \ (.\ digits \ )? \ (\ [eE\ (+\ |\ -)\ digits\ )?} \]
Recognizing REs

- Finite automata can be used to recognize strings generated by regular expressions
- Can build by hand or automatically
  - Not totally straightforward, but can be done systematically
  - Tools like Lex, Flex, Jlex et seq do this automatically, given a set of REs
Finite State Automaton

- A finite set of states
  - One marked as initial state
  - One or more marked as final states
  - States sometimes labeled or numbered
- A set of transitions from state to state
  - Each labeled with symbol from $\Sigma$, or $\varepsilon$
- Operate by reading input symbols (usually characters)
  - Transition can be taken if labeled with current symbol
  - $\varepsilon$-transition can be taken at any time
- Accept when final state reached & no more input
  - Scanner uses a FSA as a subroutine – accept longest match each time called, even if more input; i.e., run the FSA from the current location in the input each time the scanner is called
  - Reject if no transition possible, or no more input and not in final state (DFA)
Example: FSA for "cat"
DFA vs NFA

- Deterministic Finite Automata (DFA)
  - No choice of which transition to take under any condition

- Non-deterministic Finite Automata (NFA)
  - Choice of transition in at least one case
  - Accept if some way to reach final state on given input
  - Reject if no possible way to final state
FAs in Scanners

- Want DFA for speed (no backtracking)
- Conversion from regular expressions to NFA is easy
- There is a well-defined procedure for converting a NFA to an equivalent DFA
From RE to NFA: base cases

1 → 2

1 → 2

ε → 2
$rs$
From NFA to DFA

- Subset construction
  - Construct a DFA from the NFA, where each DFA state represents a set of NFA states

- Key idea
  - The state of the DFA after reading some input is the set of all states the NFA could have reached after reading the same input

- Algorithm: example of a fixed-point computation

- If NFA has \( n \) states, DFA has at most \( 2^n \) states
  - \( \Rightarrow \) DFA is finite, can construct in finite \# steps

- Resulting DFA may have more states than needed
  - See books for construction and minimization details
Example: DFA for handwritten scanner

- Idea: show a hand-written DFA for some typical programming language constructs
  - Then use to construct hand-written scanner

- Setting: Scanner is called whenever the parser needs a new token
  - Scanner stores current position in input
  - Starting there, use a DFA to recognize the longest possible input sequence that makes up a token and return that token
Scanner DFA Example (1)
Scanner DFA Example (2)
Scanner DFA Example (3)

$x = -32768$

[Diagram of a DFA]
Scanner DFA Example (4)

- Strategies for handling identifiers vs keywords
  - Hand-written scanner: look up identifier-like things in table of keywords to classify (good application of perfect hashing)
  - Machine-generated scanner: generate DFA will appropriate transitions to recognize keywords
    - Lots 'o states, but efficient (no extra lookup step)
Implementing a Scanner by Hand – Token Representation

- A token is a simple, tagged structure

```java
public class Token {
    public int kind; // token's lexical class
    public int intVal; // integer value if class = INT
    public String id; // actual identifier if class = ID
    // lexical classes
    public static final int EOF = 0; // "end of file" token
    public static final int ID = 1; // identifier, not keyword
    public static final int INT = 2; // integer
    public static final int LPAREN = 4;
    public static final int SCOLN = 5;
    public static final int WHILE = 6;
    // etc. etc. etc. ...
}
```

10/6/2009 © 2002-09 Hal Perkins & UW CSE B-40
Simple Scanner Example

// global state and methods

static char nextch;  // next unprocessed input character

// advance to next input char
void getch() { ... }

// skip whitespace and comments
void skipWhitespace() { ... }
Scanner getToken() method

// return next input token
public Token getToken() {
    Token result;
    
    skipWhiteSpace();

    if (no more input) {
        result = new Token(Token.EOF); return result;
    }

    switch(nextch) {
        case ":" result = new Token(Token.LPAREN); getch(); return result;
        case ")": result = new Token(Token.RPAREN); getch(); return result;
        case ";": result = new Token(Token.SCOLON); getch(); return result;
        // etc. ...
    }
}
getToken() (2)

    case '!' // ! or !=
       getch();
       if (nextch == '=') {
         result = new Token(Token.NEQ); getch(); return result;
       } else {
         result = new Token(Token.NOT); return result;
       }

    case '<': // < or <=
       getch();
       if (nextch == '=') {
         result = new Token(Token.LEQ); getch(); return result;
       } else {
         result = new Token(Token.LESS); return result;
       }

    // etc. ...

10/6/2009    © 2002-09 Hal Perkins & UW CSE
getToken() (3)

```java
    case '0': case '1': case '2': case '3': case '4':
    case '5': case '6': case '7': case '8': case '9':
        // integer constant
        String num = nextch;
        getch();
        while (nextch is a digit) {
            num = num + nextch; getch();
        }
    result = new Token(Token.INT, Integer(num).intValue());
    return result;
...
getToken (4)

case 'a': ... case 'z':
case 'A': ... case 'Z': // id or keyword
    string s = nextch; getch();
    while (nextch is a letter, digit, or underscore) {
        s = s + nextch; getch();
    }
    if (s is a keyword) {
        result = new Token(keywordTable.getKind(s));
    } else {
        result = new Token(Token.ID, s);
    }
    return result;
Project Notes

- For the course project (when we get there), use a lexical analyzer generator
  - Suggestion: JFlex a Java Lex-lookalike
    - Works with CUP – a Java yacc/bison implementation
    - Symbolic constant definitions for lexical classes shared between scanner/parser – customarily defined in parser input file
Coming Attractions

- Homework this week: paper exercises on regular expressions, etc.
- Next week: first part of the compiler assignment – the scanner
  - Based on the project from Ch. 2 of Appel’s book
- Next topic: parsing
  - Will do LR parsing first – use this for the project (thus CUP (Bison/YACC-like) instead of JavaCC or ANTLR)
  - Good time to start reading next chapter(s)
