CSE P 501 – Compilers

Introduction to Optimization

Hal Perkins

Winter 2016

Agenda

- Survey some code "optimizations" (improvements)
  - Get a feel for what's possible
- Some organizing concepts
  - Basic blocks
  - Control-flow and dataflow graph
  - Analysis vs. transformation

Optimizations

- Use added passes to identify inefficiencies in intermediate or target code
- Replace with equivalent but better sequences
  - Equivalent = "has same externally visible behavior"
  - Better can mean many things: faster, smaller, less power, etc.
- "Optimize" overly optimistic: "usually improve" is generally more accurate
  - And "clever" programmers can outwit you!

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

```
t1 = *(fp + ioffset);  // i
t2 = t1 * 4;
t3 = fp + t2;
t4 = *(t3 + aoffset);  // a[i]
t5 = 2;
t6 = t5 * 4;
t7 = fp + t6;
t8 = *(t7 + boffset);  // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;  // x = …
t10 = *(fp + xoffset); // x
t11 = 5;
t12 = t10 - t11;
t13 = *(fp + ioffset); // i
t14 = t13 * 4;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Strength reduction: shift often cheaper than multiply

```
t1 = *(fp + ioffset);  // i
t2 = t1 << 2;  // was t1 * 4
t3 = fp + t2;
t4 = *(t3 + aoffset);  // a[i]
t5 = 2;
t6 = t5 << 2;  // was t5 * 4
t7 = fp + t6;
t8 = *(t7 + boffset);  // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;  // x = …
t10 = *(fp + xoffset); // x
t11 = 5;
t12 = t10 - t11;
t13 = *(fp + ioffset); // i
t14 = t13 << 2; // was t13 * 4
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Constant propagation: replace variables with known constant values

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t5 = 2;
t6 = 2 << 2;   // was t5 << 2
t7 = fp + t6;
t8 = *(t7 + boffset);   // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t10 = *(fp + xoffset); // x
t11 = 5;
t12 = t10 - 5;   // was t10 - t11
t13 = *(fp + ioffset); // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Dead store (or dead assignment) elimination: remove assignments to provably unused variables

```
t1 = *(fp + ioffset);  // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);  // a[i]
t5 = 2;
t6 = 2 << 2;
t7 = fp + t6;
t8 = *(t7 + boffset);  // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;  // x = …
t10 = *(fp + xoffset); // x
t11 = 5;
t12 = t10 - 5;
t13 = *(fp + ioffset); // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Constant folding: statically compute operations with known constant values

```
t1 = *(fp + ioffset);  // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);  // a[i]
t6 = 8;  // was 2 << 2
t7 = fp + t6;
t8 = *(t7 + boffset);  // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;  // x = …
t10 = *(fp + xoffset); // x
t12 = t10 - 5;
t13 = *(fp + ioffset); // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Constant propagation then dead store elimination

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t6 = 8;
t7 = fp + 8;   // was fp + t6
t8 = *(t7 + boffset);   // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t10 = *(fp + xoffset);  // x
t12 = t10 - 5;
t13 = *(fp + ioffset);  // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12;  // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Arithmetic identities: + is commutative & associative. `boffset` is typically a known, compile-time constant (say -32), so this enables...

```
t1 = *(fp + ioffset);  // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);  // a[i]
t7 = boffset + 8;  // was fp + 8
t8 = *(t7 + fp);  // b[2] (was t7 + boffset)
t9 = t4 + t8;
*(fp + xoffset) = t9;  // x = …
t10 = *(fp + xoffset); // x
t12 = t10 - 5;
t13 = *(fp + ioffset); // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

... more constant folding,
which in turn enables ...

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t7 = -24;               // was boffset (-32) + 8
t8 = *(t7 + fp);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = ...
t10 = *(fp + xoffset);  // x
t12 = t10 - 5;
t13 = *(fp + ioffset);  // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := ...
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

More constant propagation and dead store elimination

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t7 = -24;
t8 = *(fp - 24);   // b[2]   (was t7+fp)
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t10 = *(fp + xoffset); // x
t12 = t10 - 5;
t13 = *(fp + ioffset); // i
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Common subexpression elimination – no need to compute *(fp+ioffset) again if we know it won't change

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t8 = *(fp - 24);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t10 = *(fp + xoffset);  // x
t12 = t10 - 5;
t13 = t1;        // i  (was *(fp + ioffset))
t14 = t13 << 2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Copy propagation: replace assignment targets with their values (e.g., replace t13 with t1)

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t8 = *(fp - 24);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t10 = t9;         // x (was *(fp + xoffset))
t12 = t10 - 5;
t13 = t1;               // i
t14 = t1 << 2;    // was t13 << 2
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Common subexpression elimination

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t8 = *(fp - 24);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = ...
t10 = t9;               // x
t12 = t10 - 5;
t13 = t1;               // i
t14 = t2;         // was t1 << 2
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := ...
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

More copy propagation

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t8 = *(fp - 24);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t10 = t9;               // x
t12 = t9 - 5;      // was t10 - 5
t13 = t1;               // i
t14 = t2;
t15 = fp + t14;
*(t15 + coffset) = t12; // c[i] := …
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

More copy propagation

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t8 = *(fp - 24);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = ...
t10 = t9;               // x
t12 = t9 - 5;
t13 = t1;               // i
t14 = t2;
t15 = fp + t2;  // was fp + t14
*(t15 + coffset) = t12; // c[i] := ...
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

Dead assignment elimination

```
t1 = *(fp + ioffset);  // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);  // a[i]
t8 = *(fp - 24);       // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;  // x = ...
t10 = t9;          // x
t12 = t9 - 5;
t13 = t1;          // i
t14 = t2;
t15 = fp + t2;
*(t15 + coffset) = t12; // c[i] := ...
```

An example

```
x = a[i] + b[2];
c[i] = x - 5;
```

```
t1 = *(fp + ioffset);   // i
t2 = t1 << 2;
t3 = fp + t2;
t4 = *(t3 + aoffset);   // a[i]
t8 = *(fp - 24);        // b[2]
t9 = t4 + t8;
*(fp + xoffset) = t9;   // x = …
t12 = t9 - 5;
t15 = fp + t2;
*(t15 + coffset) = t12; // c[i] := …
```

- Final: 3 loads (i, a[i], b[2]), 2 stores (x, c[i]), 5 register-only moves, 9 +/-, 1 shift
- Original: 5 loads, 2 stores, 10 register-only moves, 12 +/-, 3 *

- Optimizer note: we usually leave assignment of actual registers to later stage of the compiler and assume as many "pseudo registers" as we need here

Kinds of optimizations

- peephole: look at adjacent instructions
- local: look at individual *basic blocks*
  - straight-line sequence of statements
- intraprocedural: look at whole procedure
  - Commonly called “global”
- interprocedural: look across procedures
  - “whole program” analysis
  - gcc’s “link time optimization” is a version of this
- Larger scope => usually better optimization but more cost and complexity
  - Analysis is often less precise because of more possibilities

Peephole Optimization

- After target code generation, look at adjacent instructions (a "peephole" on the code stream)
  - try to replace adjacent instructions with something faster

`movq %r9,16(%rsp)` `movq 16(%rsp),%r12`	`movq %r9,16(%rsp)` `movq %r9,%r12`

  - Jump chaining can also be considered a form of peephole optimization (removing jump to jump)

More Examples

`subq $8,%rax`
`movq %r2,0(%rax)`
`# %rax overwritten`
	`movq %r2,-8(%rax)`

`movq 16(%rsp),%rax`
`addq $1,%rax`
`movq %rax,16(%rsp)`
`# %rax overwritten`
	`incq 16(%rsp)`

- One way to do complex instruction selection

Algebraic Simplification

- "constant folding", "strength reduction"
  - `z = 3 + 4;` → `z = 7`
  - `z = x + 0;` → `z = x`
  - `z = x * 1;` → `z = x`
  - `z = x * 2;` → `z = x << 1   or z = x + x`
  - `z = x * 8;` → `z = x << 3`
  - `z = x / 8;` → `z = x >> 3 (only if x>=0 known)`
  - `z = (x + y) - y;` → `z = x (maybe; not doubles, might change int overflow)`
- Can be done at many levels from peephole on up
- Why do these examples happen?
  - Often created during conversion to lower-level IR, by other optimizations, code gen, etc.

Local Optimizations

- Analysis and optimizations within a basic block
- *Basic block*: straight-line sequence of statements
  - no control flow into or out of middle of sequence
- Better than peephole
- Not too hard to implement with reasonable IR

- Machine-independent, if done on IR

Local Constant Propagation

- If variable assigned a constant, replace downstream uses of the variable with constant (until variable reassigned)
- Can enable more constant folding
  - Code; unoptimized intermediate code:

`count = 10;`
`...  // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = count;`
	`t2 = 5;`
	`t3 = t1 * t2;`
	`x = t3;`
	`t4 = x;`
	`t5 = 3;`
	`t6 = exp(t4,t5);`
	`y = t6;`
	`x = 7`

Local Constant Propagation

- If variable assigned a constant, replace downstream uses of the variable with constant (until variable reassigned)
- Can enable more constant folding
  - Code; constant propagation:

<pre>count = 10;
... // count not changed
x = count * 5;
y = x ^ 3;
x = 7;</pre>
	<pre>count = 10;
	t1 = 10; // cp count
	t2 = 5;
	t3 = 10 * t2; // cp t1
	x = t3;
	t4 = x;
	t5 = 3;
	t6 = exp(t4,3); // cp t5
	y = t6;
	x = 7</pre>

Local Constant Propagation

- If variable assigned a constant, replace downstream uses of the variable with constant (until variable reassigned)
- Can enable more constant folding
  - Code; constant folding:

`count = 10;`
`... // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = 10;`
	`t2 = 5;`
	`t3 = 50;   // 10*t2`
	`x = t3;`
	`t4 = x;`
	`t5 = 3;`
	`t6 = exp(t4,3);`
	`y = t6;`
	`x = 7;`

Local Constant Propagation

- If variable assigned a constant, replace downstream uses of the variable with constant (until variable reassigned)
- Can enable more constant folding
  - Code; repropagated intermediate code

`count = 10;`
`... // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = 10;`
	`t2 = 5;`
	`t3 = 50;`
	`x = 50;    // cp t3`
	`t4 = 50;   // cp x`
	`t5 = 3;`
	`t6 = exp(50,3); // cp t4`
	`y = t6;`
	`x = 7;`

Local Constant Propagation

- If variable assigned a constant, replace downstream uses of the variable with constant (until variable reassigned)
- Can enable more constant folding
  - Code; refold intermediate code

`count = 10;`
`... // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = 10;`
	`t2 = 5;`
	`t3 = 50;`
	`x = 50;`
	`t4 = 50;`
	`t5 = 3;`
	`t6 = 125000; // cf 50^3`
	`y = t6;`
	`x = 7;`

Local Constant Propagation

- If variable assigned a constant, replace downstream uses of the variable with constant (until variable reassigned)
- Can enable more constant folding
  - Code; repropagated intermediate code

`count = 10;`
`... // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = 10;`
	`t2 = 5;`
	`t3 = 50;`
	`x = 50;`
	`t4 = 50;`
	`t5 = 3;`
	`t6 = 125000;`
	`y = 125000; // cp t6`
	`x = 7;`

Local Dead Assignment Elimination

- If l.h.s. of assignment never referenced again before being overwritten, then can delete assignment
  - Why would this happen?
    Clean-up after previous optimizations, often

`count = 10;`
`...  // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = 10;`
	`t2 = 5;`
	`t3 = 50;`
	`x = 50;`
	`t4 = 50;`
	`t5 = 3;`
	`t6 = 125000;`
	`y = 125000;`
	`x = 7;`

Local Dead Assignment Elimination

- If l.h.s. of assignment never referenced again before being overwritten, then can delete assignment
  - Why would this happen?
    CleaQ-up after previous optimizations, often

`count = 10;`
`...  // count not changed`
`x = count * 5;`
`y = x ^ 3;`
`x = 7;`
	`count = 10;`
	`t1 = 10;`
	~~`t2 = 5;`~~
	~~`t3 = 50;`~~
	~~`x = 50;`~~
	~~`t4 = 50;`~~
	~~`t5 = 3;`~~
	~~`t6 = 125000;`~~
	`y = 125000;`
	`x = 7;`

Local Common Subexpression Elimination

- Look for repetitions of the same computation. Eliminate them if result won't have changed and no side effects
  - Avoid repeated calculation and eliminates redundant loads
- Idea: walk through basic block keeping track of available expressions

`... a[i] + b[i] ...`	`t1 = *(fp + ioffset);`
	`t2 = t1 * 4;`
	`t3 = fp + t2;`
	`t4 = *(t3 + aoffset);`
	`t5 = *(fp + ioffset);`
	`t6 = t5 * 4;`
	`t7 = fp + t6;`
	`t8 = *(t7 + boffset);`
	`t9 = t4 + t8;`

Local Common Subexpression Elimination

- Look for repetitions of the same computation. Eliminate them if result won't have changed and no side effects
  - Avoid repeated calculation and eliminates redundant loads
- Idea: walk through basic block keeping track of available expressions

`... a[i] + b[i] ...`	`t1 = *(fp + ioffset);`
	`t2 = t1 * 4;`
	`t3 = fp + t2;`
	`t4 = *(t3 + aoffset);`
	`t5 = t1;   // CSE`
	`t6 = t5 * 4;`
	`t7 = fp + t6;`
	`t8 = *(t7 + boffset);`
	`t9 = t4 + t8;`

Local Common Subexpression Elimination

- Look for repetitions of the same computation. Eliminate them if result won't have changed and no side effects
  - Avoid repeated calculation and eliminates redundant loads
- Idea: walk through basic block keeping track of available expressions

`... a[i] + b[i] ...`	`t1 = *(fp + ioffset);`
	`t2 = t1 * 4;`
	`t3 = fp + t2;`
	`t4 = *(t3 + aoffset);`
	`t5 = t1;`
	`t6 = t1 * 4;   // CP`
	`t7 = fp + t6;`
	`t8 = *(t7 + boffset);`
	`t9 = t4 + t8;`

Local Common Subexpression Elimination

- Look for repetitions of the same computation. Eliminate them if result won't have changed and no side effects
  - Avoid repeated calculation and eliminates redundant loads
- Idea: walk through basic block keeping track of available expressions

`... a[i] + b[i] ...`	`t1 = *(fp + ioffset);`
	`t2 = t1 * 4;`
	`t3 = fp + t2;`
	`t4 = *(t3 + aoffset);`
	`t5 = t1;`
	`t6 = t2;      // CSE`
	`t7 = fp + t2; // CP`
	`t8 = *(t7 + boffset);`
	`t9 = t4 + t8;`

Local Common Subexpression Elimination

- Look for repetitions of the same computation. Eliminate them if result won't have changed and no side effects
  - Avoid repeated calculation and eliminates redundant loads
- Idea: walk through basic block keeping track of available expressions

`... a[i] + b[i] ...`	`t1 = *(fp + ioffset);`
	`t2 = t1 * 4;`
	`t3 = fp + t2;`
	`t4 = *(t3 + aoffset);`
	`t5 = t1;`
	`t6 = t2;`
	`t7 = t3;  // CSE`
	`t8 = *(t3 + boffset); //CP`
	`t9 = t4 + t8;`

Local Common Subexpression Elimination

- Look for repetitions of the same computation. Eliminate them if result won't have changed and no side effects
  - Avoid repeated calculation and eliminates redundant loads
- Idea: walk through basic block keeping track of available expressions

`... a[i] + b[i] ...`	`t1 = *(fp + ioffset);`
	`t2 = t1 * 4;`
	`t3 = fp + t2;`
	`t4 = *(t3 + aoffset);`
	~~`t5 = t1;`~~ `// DAE`
	~~`t6 = t2;`~~ `// DAE`
	~~`t7 = t3;`~~ `// DAE`
	`t8 = *(t3 + boffset);`
	`t9 = t4 + t8;`

Intraprocedural optimizations

- Enlarge scope of analysis to whole procedure
  - more opportunities for optimization
  - have to deal with branches, merges, and loops
- Can do constant propagation, common subexpression elimination, etc. at "global" level
- Can do new things, e.g. loop optimizations
- Optimizing compilers usually work at this level (-O2)

Code Motion

- Goal: move loop-invariant calculations out of loops
- Can do at source level or at intermediate code level

```
for (i = 0; i < 10; i = i+1) {
  a[i] = a[i] + b[j];
  z = z + 10000;
}
```

```
t1 = b[j];
t2 = 10000;
for (i = 0; i < 10; i = i+1) {
  a[i] = a[i] + t1;
  z = z + t2;
}
```

Q-40

Code Motion at IL

```
for (i = 0; i < 10; i = i+1) {
  a[i] = b[j];
}
```

```
 *(fp + ioffset) = 0;
label top;
  t0 = *(fp + ioffset);
  iffalse (t0 < 10) goto done;
  t1 = *(fp + joffset);
  t2 = t1 * 4;
  t3 = fp + t2;
  t4 = *(t3 + boffset);
  t5 = *(fp + ioffset);
  t6 = t5 * 4;
  t7 = fp + t6;
  *(t7 + aoffset) = t4;
  t9 = *(fp + ioffset);
  t10 = t9 + 1;
  *(fp + ioffset) = t10;
  goto top;
label done;
```

Code Motion at IL

```
for (i = 0; i < 10; i = i+1) {
  a[i] = b[j];
}
```

```
t11 = fp + ioffset; t13 = fp + aoffset;
t12 = fp + joffset; t14 = fp + boffset
*(fp + ioffset) = 0;
label top;
  t0 = *t11;
  iffalse (t0 < 10) goto done;
  t1 = *t12;
  t2 = t1 * 4;
  t3 = t14;
  t4 = *(t14 + t2);
  t5 = *t11;
  t6 = t5 * 4;
  t7 = t13;
  *(t13 + t6) = t4;
  t9 = *t11;
  t10 = t9 + 1;
  *t11 = t10;
  goto top;
label done;
```

Q-42

Loop Induction Variable Elimination

- A special and common case of loop-based strength reduction
- For-loop index is *induction variable*
  - incremented each time around loop
  - offsets & pointers calculated from it
- If used only to index arrays, can rewrite with pointers
  - compute initial offsets/pointers before loop
  - increment offsets/pointers each time around loop
  - no expensive scaling in loop
  - can then do loop-invariant code motion

```
for (i = 0; i < 10; i = i+1) {
  a[i] = a[i] + x;
}
```

=> transformed to

```
for (p = &a[0]; p < &a[10]; p = p+4) {
  *p = *p + x;
}
```

Interprocedural Optimization

- Expand scope of analysis to procedures calling each other
- Can do local & intraprocedural optimizations at larger scope
- Can do new optimizations, e.g. inlining

Inlining: replace call with body

- Replace procedure call with body of called procedure
- Source:

```
final double pi = 3.1415927;
double circle_area(double radius) {
   return pi * (radius * radius);
}
...
double r = 5.0;
...
double a = circle_area(r);
```

- After inlining:

```
...
double r = 5.0;
...
double a = pi * r * r;
```

- (Then what? Constant propagation/folding)

Data Structures for Optimizations

- Need to represent control and data flow
- Control flow graph (CFG) captures flow of control
  - nodes are IL statements, or whole basic blocks
  - edges represent (all possible) control flow
  - node with multiple successors = branch/switch
  - node with multiple predecessors = merge
  - loop in graph = loop
- Data flow graph (DFG) captures flow of data, e.g. def/use chains:
  - nodes are def(inition)s and uses
  - edge from def to use
  - a def can reach multiple uses
  - a use can have multiple reaching defs (different control flow paths, possible aliasing, etc.)
- SSA: another widely used way of linking defs and uses

Analysis and Transformation

- Each optimization is made up of
  - some number of analyses
  - followed by a transformation
- Analyze CFG and/or DFG by propagating info forward or backward along CFG and/or DFG edges
  - merges in graph require combining info
  - loops in graph require *iterative approximation*
- Perform (improving) transformations based on info computed
- Analysis must be conservative/safe/sound so that transformations preserve program behavior

Summary

- Optimizations organized as collections of passes, each rewriting IL in place into (hopefully) better version
- Each pass does analysis to determine what is possible, followed by transformation(s) that (hopefully) improve the program
  - Sometimes "analysis-only" passes are helpful
  - Often redo analysis/transformations again to take advantage of possibilities revealed by previous changes
- Presence of optimizations makes other parts of compiler (e.g. intermediate and target code generation) easier to write
