# Dynamic Typing (review)

JavaScript:

```
function foo(a, b) {  
  t1 = a.x;      // runtime field lookup  
  t2 = b.y();   // runtime method lookup  
  t3 = t1 + t2; // runtime dispatch on '+'  
  return t3;  
}
```

# Overview

- Self
  - 35(!) year old research language
  - One of earliest JIT compilation systems
  - Pioneered techniques used today
- JavaScript
  - Self with a Java syntax (plus other things...)
  - Lots of interest in making it fast in recent years

# Self

- Prototype-based pure object-oriented language
- Designed by Randall Smith (Xerox PARC) and David Ungar (Stanford University)
  - Successor to Smalltalk-80
  - “Self: The power of simplicity” at OOPSLA ‘87
  - Initial implementation done at Stanford; then project shifted to Sun Microsystems Labs
  - Vehicle for implementation research
- Current version available from [selflanguage.org](http://selflanguage.org)

# Design Goals

- Occam's Razor: Conceptual economy
  - Everything is an object.
  - Everything done using messages.
  - No classes
  - No variables
- Concreteness
  - Objects should seem “real”
  - GUI to manipulate objects directly

# How successful?

- Very well-designed language, but...
- Few users: not a popular success
- However, many research innovations
  - Very simple computational model
  - Enormous advances in compilation techniques
  - Influenced the design of Java compilers
  - JavaScript object model based on Self

# Language Overview

- Dynamically typed
- Everything is an object
- All computation via message passing
- Creation and initialization done by copying example (prototype) object
- Operations on objects:
  - send messages
  - add new slots
  - replace old slots
  - remove slots

# Objects and Slots

Object consists of named slots.

– Data

- Such slots return contents upon evaluation; so act like variables

– Assignment

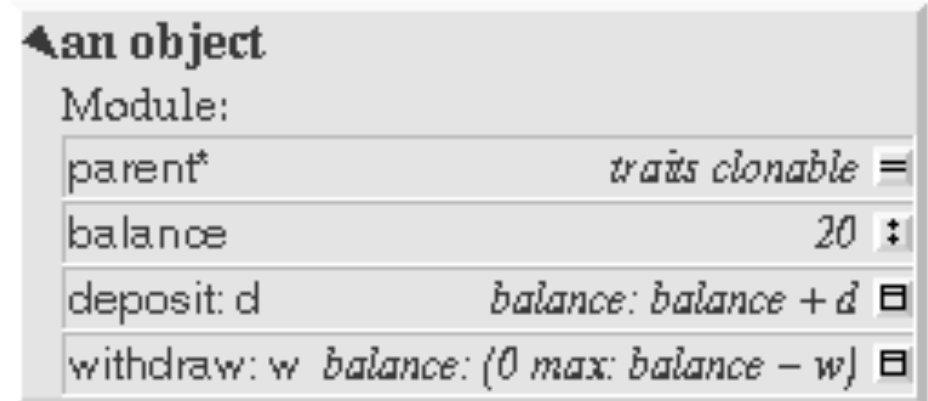

- Set the value of associated slot

– Method

- Slot contains Self code

– Parent

- References an object to inherit its slots

←an object

Module:	
parent*	<i>traits clonable</i> =
balance	20 *
deposit: d	<i>balance: balance + d</i> □
withdraw: w	<i>balance: (0 max: balance - w)</i> □

# Messages and Methods

- When a message is sent, search the receiver object for a slot with that name
- If none found, all parents are searched
  - Runtime error if more than one parent has a slot with the same name
- If slot found, its contents are evaluated and returned
  - Runtime error if no slot found

# Messages and Methods

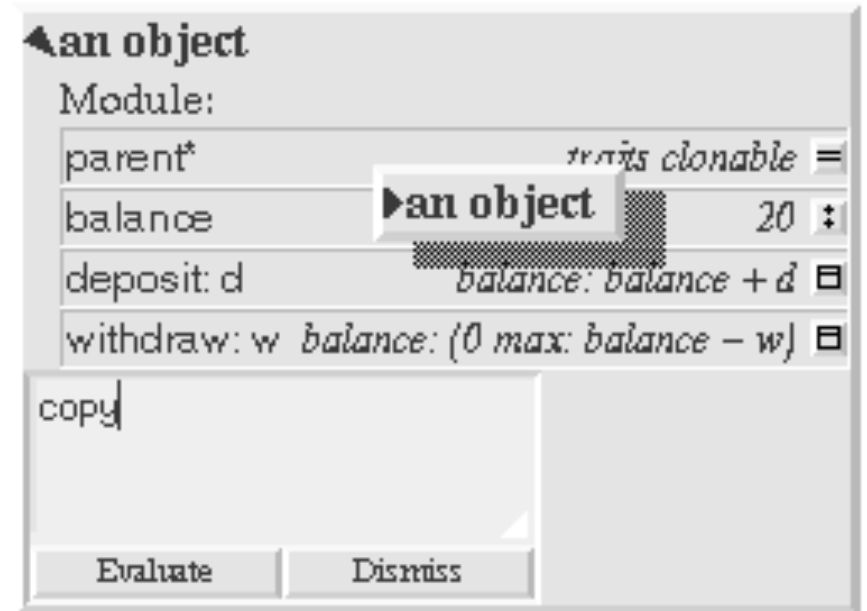

# Mixing State and Behavior

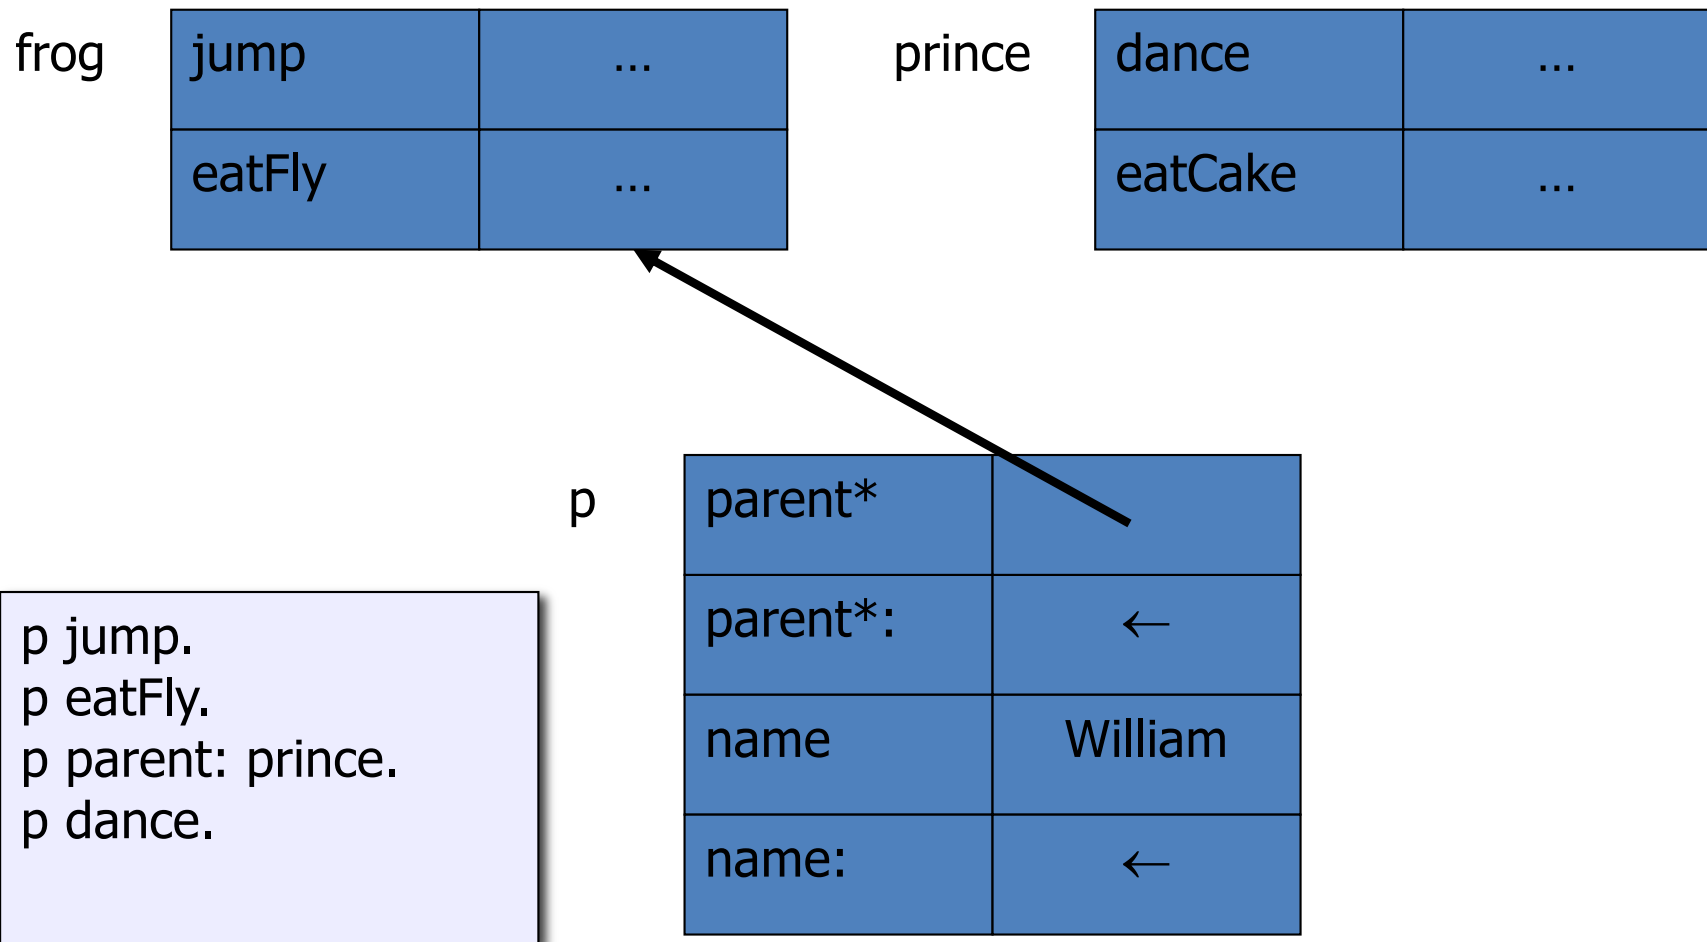

# Object Creation

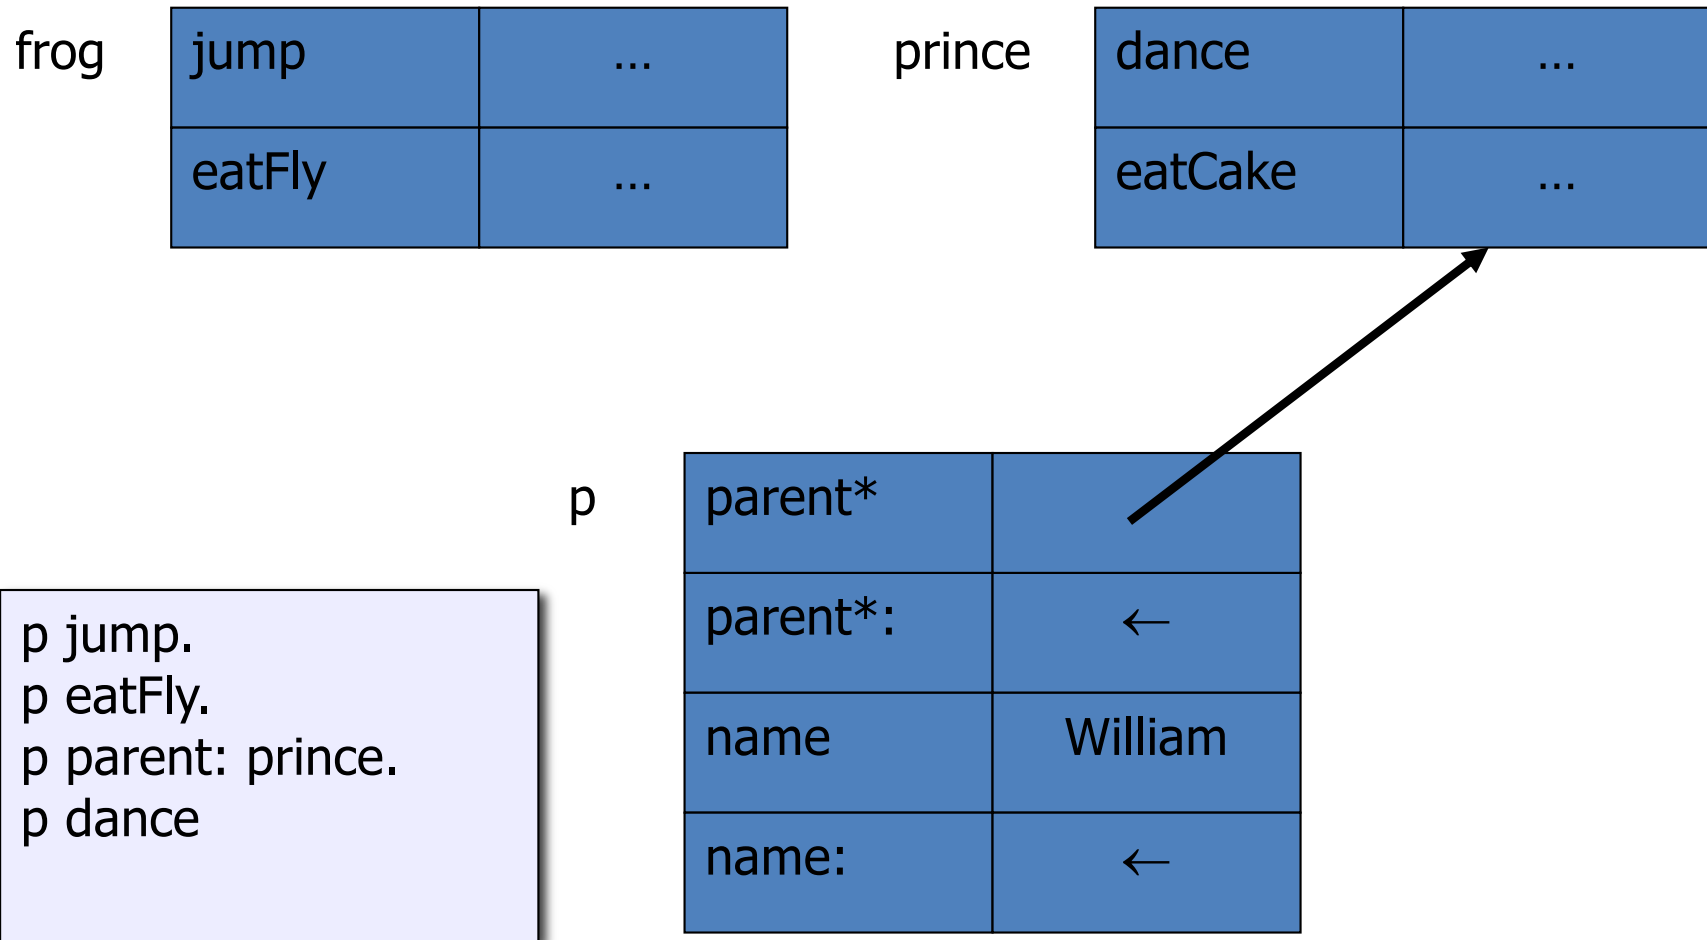

- To create an object, we copy an old one
- We can **add** new methods, **override** existing ones, or even **remove** methods
- These operations also apply to **parent** slots

# Changing Parent Pointers

# Changing Parent Pointers

# Disadvantages of classes?

- Classes require programmers to understand a more complex model
  - To make a new kind of object, we have to create a new class first
  - To change an object, we have to change the class
  - Infinite meta-class regression (What is the class of a class? Or: Is a class an object, and if not, what is it?)
- **But:** Does Self require programmers to reinvent structure?
  - Common to structure Self programs with *traits*: objects that simply collect behavior for sharing

# Contrast with C++ / Java

- C++ / Java
  - Restricts expressiveness to ensure efficient implementation
- Self
  - Provides unbreakable high-level model of underlying machine
  - Compiler does fancy optimizations to obtain acceptable performance

# Implementation Challenges I

- Many, many slow function calls:
  - Function calls generally somewhat expensive
  - Dynamic dispatch makes message invocation even slower than typical procedure calls
  - OO programs tend to have lots of small methods
  - Everything is a message: even variable access!

“The resulting call density of pure object-oriented programs is staggering, and brings naïve implementations to their knees” [Chambers & Ungar, PLDI 89]

# Implementation Challenges II

- No static type system
  - Each reference could point to any object, making it hard to find methods statically
- No class structure to enforce sharing
  - Copies of methods in every object creates lots of space overhead

Optimized Smalltalk-80 is roughly 10 times slower than optimized C

# Optimization Strategies

- Avoid per-object space requirements
- Compile, don't interpret
- Avoid method lookup
- Inline methods wherever possible
  - Saves method call overhead
  - Enables further optimizations

# Clone Families

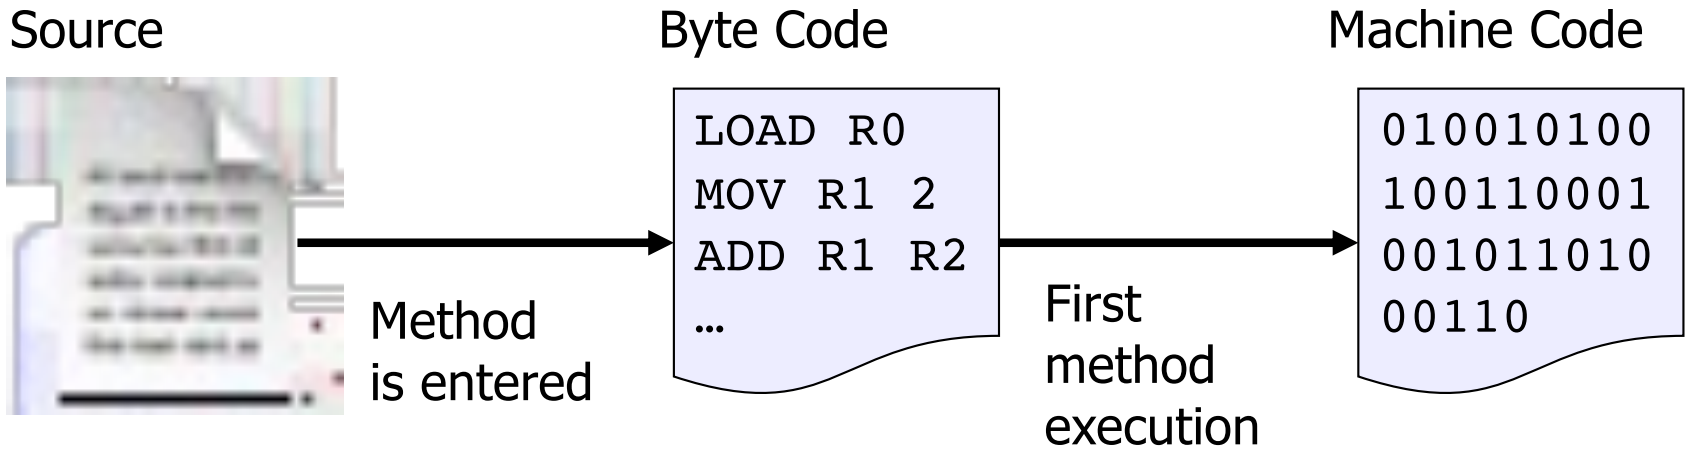

(Objects created from same prototype)

Avoid per object data

Avoid interpreting

# Dynamic Compilation

- Method is converted to byte codes when entered into the system
- Compiled to machine code when first executed
- Code stored in cache
  - if cache fills, previously compiled method flushed
- Requires entire source (byte) code to be available at runtime

# Lookup Cache

- Cache of recently used methods, indexed by (receiver type, message name) pairs
- When a message is sent, compiler first consults cache
  - if found: invokes associated code
  - if absent: performs general lookup and potentially updates cache
- Berkeley Smalltalk would have been 37% slower without this optimization

# Static Type Prediction

- Compiler predicts types that are unknown but likely:
  - Arithmetic operations (+, -, <, *etc.*) have small integers as their receivers 95% of time in Smalltalk-80
  - ifTrue had Boolean receiver 100% of the time.
- Compiler inlines code (and test to confirm guess):

```
if type = smallInt jump to method_smallInt  
call general_lookup
```

# Inline Caches

- First message send from a *call site* :
  - general lookup routine invoked & backpatch
- Call site back-patched previously
  - is previous method still correct?
    - yes: invoke code directly
    - no: proceed with general lookup & backpatch
- Successful about 95% of the time
- All compiled implementations of Smalltalk and Self use inline caches.

# Polymorphic Inline Caches

- Typical call site has <10 distinct receiver types
  - Often can cache *all* receivers
- At each call site, for each new receiver, extend patch code:

```
if type = rectangle jump to method_rect
if type = circle     jump to method_circle
call general_lookup
```

- After some threshold, revert to simple inline cache (**megamorphic site**)
- Order clauses by frequency
- Inline short methods into PIC code

# Customized Compilation

- Compile several copies of each method, one for each receiver type
- Within each copy:
  - Compiler knows the type of self
  - Calls through self can be statically selected and inlined
- Enables downstream optimizations
- Increases code size

# Type Analysis

- Constructed by compiler using flow analysis
- Type: set of possible maps for object
  - Singleton: know map statically
  - Union/Merge: know expression has one of a fixed collection of maps
  - Unknown: know nothing about expression
- If singleton, we can inline method
- If type is small, we can insert type test and create branch for each possible receiver (**type casing**)

# Message Splitting

- Type information above a merge point is often better
- Move message send “before” merge point:
  - duplicates code
  - improves type information
  - allows more inlining

# PICS as Type Source

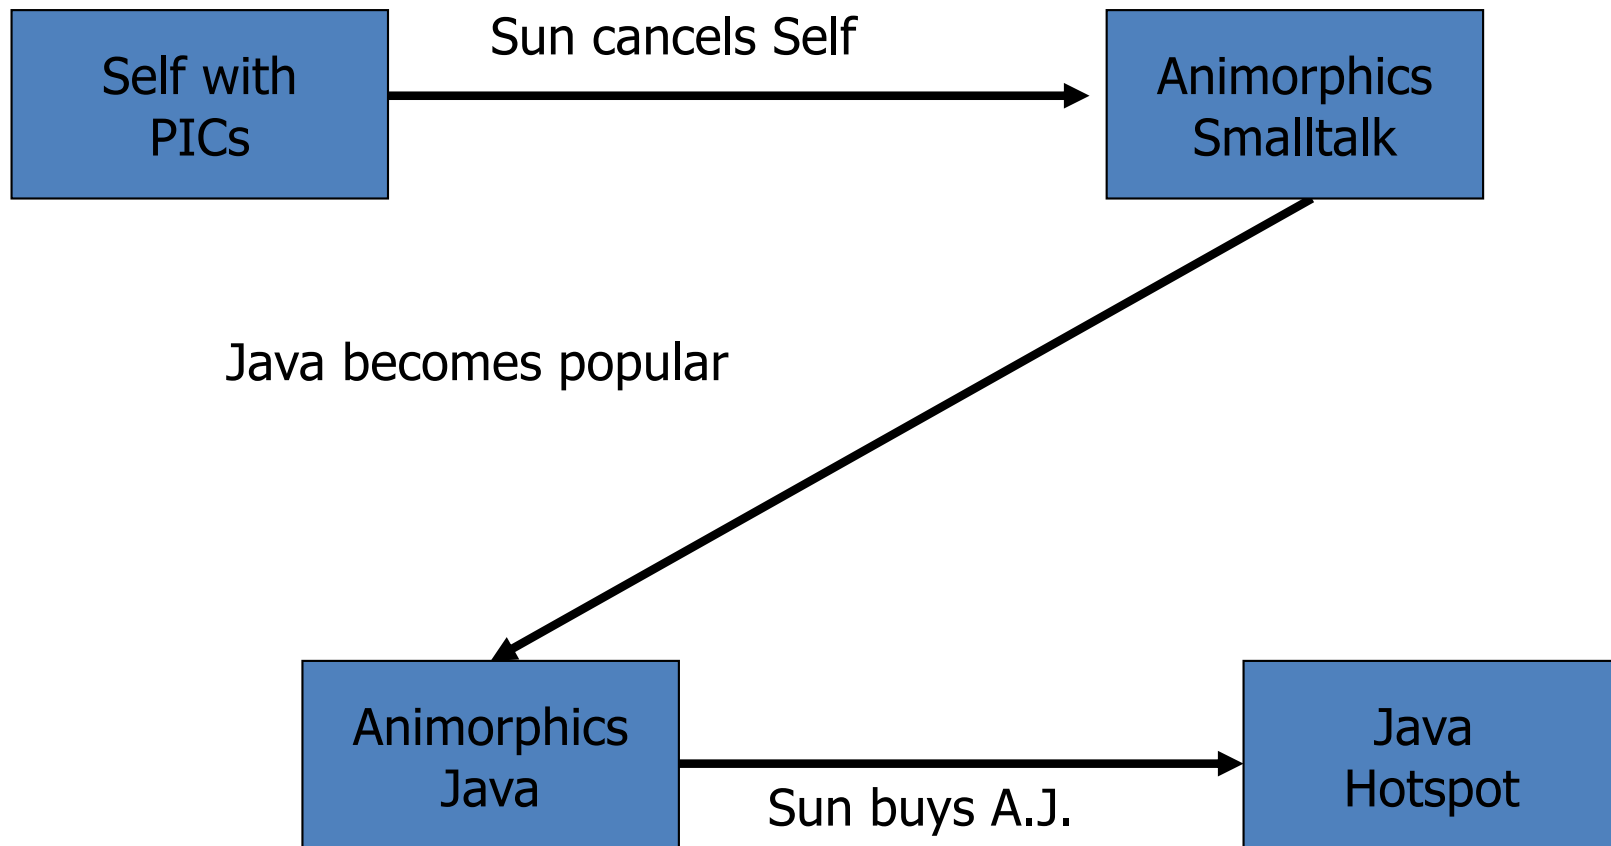

- Polymorphic inline caches build a call-site specific type database *as the program runs*
- Compiler can use this runtime information rather than the result of a static flow analysis to build *type cases*
- Must wait until PIC has collected information
  - When to recompile?
  - What should be recompiled?
- Initial fast compile yielding slow code; then dynamically recompile – *hotspots*

# Performance Improvements

- Initial version of Self was 4-5 times slower than optimized C
- Adding **type analysis** and **message splitting** got within a factor of 2 of optimized C
- Replacing type analysis with **PICS** improved performance by further 37%

Fairly recent Self compiler is within a factor of 2 of optimized C.

# Impact on Java

# Summary of Self

- “Power of simplicity”
  - Everything is an object: no classes, no variables
  - Provides high-level model that can’t be violated (even during debugging)
- Fancy optimizations recover reasonable performance
- Many techniques now used in Java compilers
- Papers describing various optimization techniques available from Self web site

# JavaScript

- Self-like language with Java syntax
  - Dynamic OO language
  - Prototypes instead of classes
  - Nothing to do with Java beyond syntax
- Originated in Netscape
- “Standard” on today’s browsers

# High-performance JavaScript

- Self approach:
  - V8 (Google Chrome)
  - SquirrelFish Extreme (Safari / WebKit)
- Trace compilation:
  - TraceMonkey (Firefox)
  - Tamarin (Adobe Flash/Flex)

# V8 (Google Chrome)

- Three primary features
  - Fast property access
    - Hidden classes
  - Dynamic compiler
    - Compile on first invocation
    - Inline caching with back patching
  - Generational garbage collection
    - Segmented by types
- See <http://code.google.com/apis/v8/design.html>

# Trace-Based Compilation

- Interpret initially
- Record trace information
  - Single entry, multiple exit
  - Loop header is typically trace start
- Compile hot trace (hot path through flowgraph)
  - Interpreter jumps to trace code when available
  - Stitch multiple traces together
- Specialize hot path (omit redundant checks)
  - Claim this achieves benefits of inline caching

# Conclusions?

- For you to decide...
