  - Chapter 2.1, 2.2
  - Chapter 3
  - Chapter 4
- Homework Guidelines
  - Prove that your algorithm works
    - A proof is a “convincing argument”
  - Give the run time for you algorithm
    - Justify that the algorithm satisfies the runtime bound
  - You may lose points for style

# Announcements

- Monday, January 21 is a holiday
  - No class
- Makeup lecture, Thursday, January 17, 5:00 pm – 6:30 pm
  - UW and Microsoft
  - View off line if you cannot attend
- Homework 2 is due January 21
  - Electronic turn in only

What does it mean for an algorithm  
to be efficient?

# Definitions of efficiency

- Fast in practice
- Qualitatively better worst case performance than a brute force algorithm

# Polynomial time efficiency

- An algorithm is efficient if it has a polynomial run time
- Run time as a function of problem size
  - Run time: count number of instructions executed on an underlying model of computation
  - $T(n)$ : maximum run time for all problems of size at most  $n$

# Polynomial Time

- Algorithms with polynomial run time have the property that increasing the problem size by a constant factor increases the run time by at most a constant factor (depending on the algorithm)

# Why Polynomial Time?

- Generally, polynomial time seems to capture the algorithms which are efficient in practice
- The class of polynomial time algorithms has many good, mathematical properties

# Polynomial vs. Exponential Complexity

- Suppose you have an algorithm which takes  $n!$  steps on a problem of size  $n$
- If the algorithm takes one second for a problem of size 10, estimate the run time for the following problems sizes:

12

14

16

18

20

# Ignoring constant factors

- Express run time as  $O(f(n))$
- Emphasize algorithms with slower growth rates
- Fundamental idea in the study of algorithms
- Basis of Tarjan/Hopcroft Turing Award

# Why ignore constant factors?

- Constant factors are arbitrary
  - Depend on the implementation
  - Depend on the details of the model
- Determining the constant factors is tedious and provides little insight

# Why emphasize growth rates?

- The algorithm with the lower growth rate will be faster for all but a finite number of cases
- Performance is most important for larger problem size
- As memory prices continue to fall, bigger problem sizes become feasible
- Improving growth rate often requires new techniques

# Formalizing growth rates

- $T(n)$  is  $O(f(n))$                        $[T : \mathbb{Z}^+ \rightarrow \mathbb{R}^+]$ 
  - If  $n$  is sufficiently large,  $T(n)$  is bounded by a constant multiple of  $f(n)$
  - Exist  $c, n_0$ , such that for  $n > n_0$ ,  $T(n) < c f(n)$
- $T(n)$  is  $O(f(n))$  will be written as:  
 $T(n) = O(f(n))$ 
  - Be careful with this notation

Prove  $3n^2 + 5n + 20$  is  $O(n^2)$

Let  $c =$

Let  $n_0 =$

$T(n)$  is  $O(f(n))$  if there exist  $c, n_0$ , such that for  $n > n_0$ ,  
 $T(n) < c f(n)$

Order the following functions in increasing order by their growth rate

a)  $n \log^4 n$

b)  $2n^2 + 10n$

c)  $2^{n/100}$

d)  $1000n + \log^8 n$

e)  $n^{100}$

f)  $3^n$

g)  $1000 \log^{10} n$

h)  $n^{1/2}$

# Lower bounds

- $T(n)$  is  $\Omega(f(n))$ 
  - $T(n)$  is at least a constant multiple of  $f(n)$
  - There exists an  $n_0$ , and  $\varepsilon > 0$  such that  $T(n) > \varepsilon f(n)$  for all  $n > n_0$
- Warning: definitions of  $\Omega$  vary
- $T(n)$  is  $\Theta(f(n))$  if  $T(n)$  is  $O(f(n))$  and  $T(n)$  is  $\Omega(f(n))$

# Useful Theorems

- If  $\lim (f(n) / g(n)) = c$  for  $c > 0$  then  $f(n) = \Theta(g(n))$
- If  $f(n)$  is  $O(g(n))$  and  $g(n)$  is  $O(h(n))$  then  $f(n)$  is  $O(h(n))$
- If  $f(n)$  is  $O(h(n))$  and  $g(n)$  is  $O(h(n))$  then  $f(n) + g(n)$  is  $O(h(n))$

# Ordering growth rates

- For  $b > 1$  and  $x > 0$ 
  - $\log^b n$  is  $O(n^x)$
- For  $r > 1$  and  $d > 0$ 
  - $n^d$  is  $O(r^n)$

# Stable Matching

# Reported Results

<b>Student</b>	<b>n</b>	<b>M / n</b>	<b>W / n</b>	<b>M / n * W / n</b>
Stanislav	10,000	9.96	1020	10159

Why is  $M/n \sim \log n$ ?

Why is  $W/n \sim n / \log n$ ?

# Graph Theory

# Graph Theory

- $G = (V, E)$ 
  - $V$  – vertices
  - $E$  – edges
- Undirected graphs
  - Edges sets of two vertices  $\{u, v\}$
- Directed graphs
  - Edges ordered pairs  $(u, v)$
- Many other flavors
  - Edge / vertices weights
  - Parallel edges
  - Self loops

# Definitions

- Path:  $v_1, v_2, \dots, v_k$ , with  $(v_i, v_{i+1})$  in  $E$ 
  - Simple Path
  - Cycle
  - Simple Cycle
- Distance
- Connectivity
  - Undirected
  - Directed (strong connectivity)
- Trees
  - Rooted
  - Unrooted

# Graph search

- Find a path from  $s$  to  $t$

$S = \{s\}$

While there exists  $(u, v)$  in  $E$  with  $u$  in  $S$  and  $v$  not in  $S$

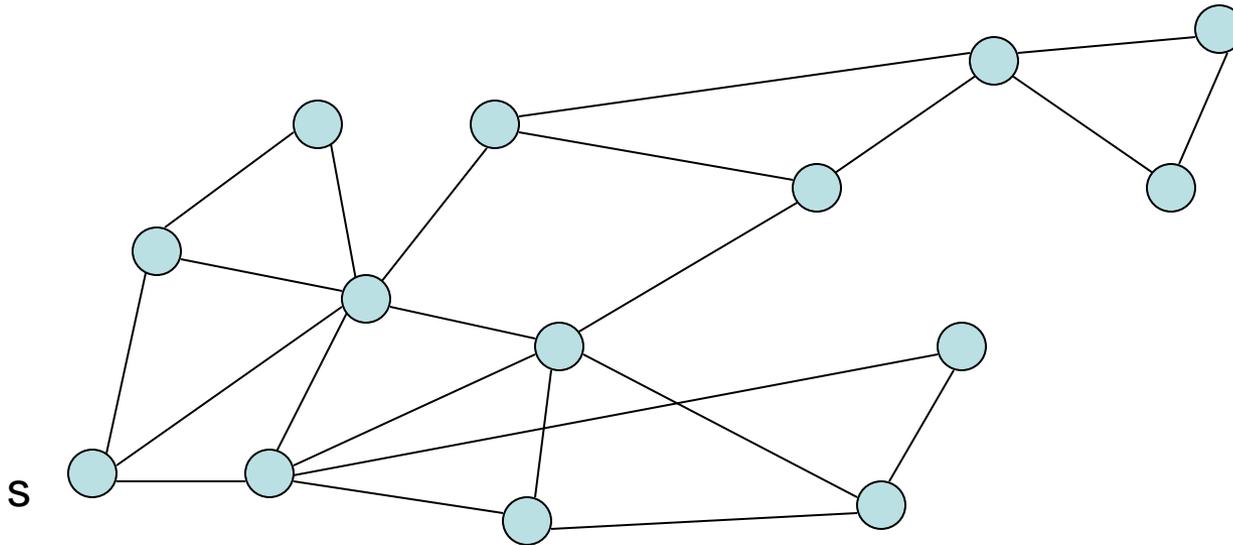

$\text{Pred}[v] = u$

    Add  $v$  to  $S$

    if  $(v = t)$  then path found

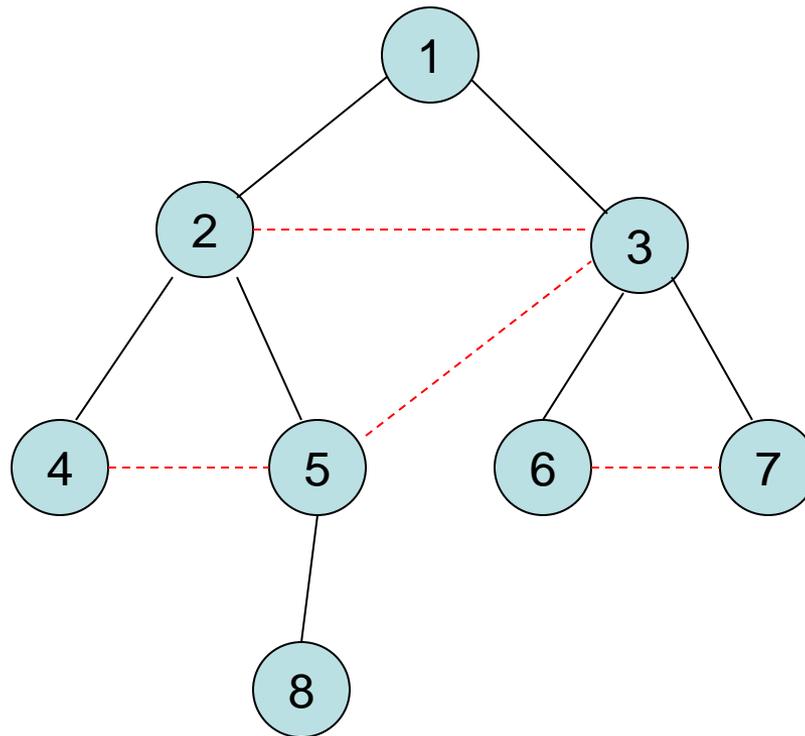

# Breadth first search

- Explore vertices in layers
  - $s$  in layer 1
  - Neighbors of  $s$  in layer 2
  - Neighbors of layer 2 in layer 3 . . .

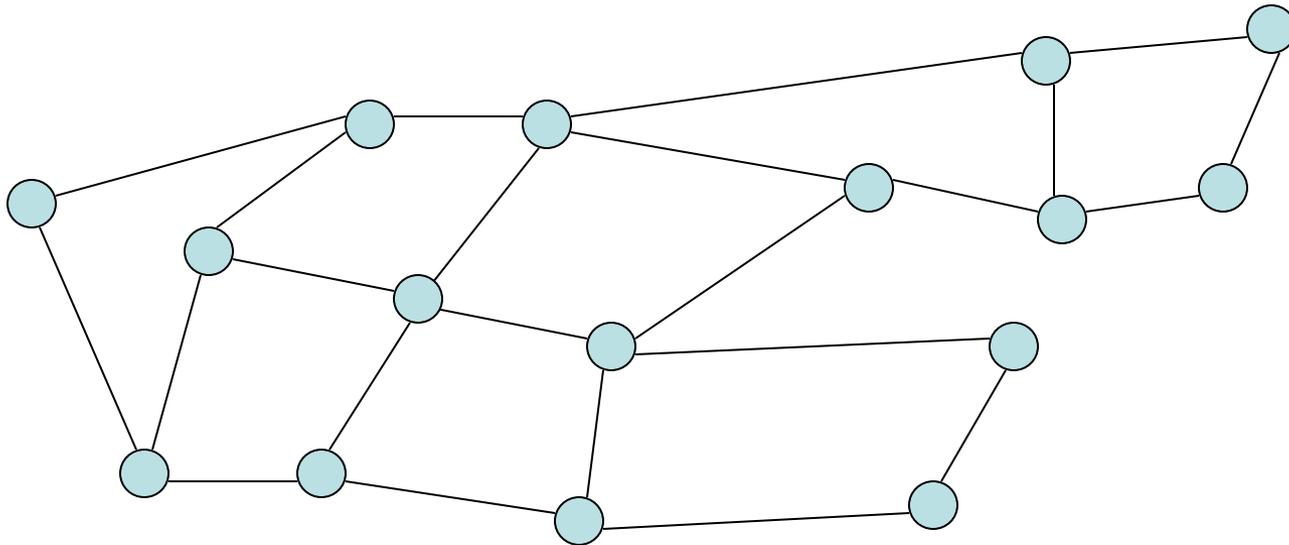

# Key observation

- All edges go between vertices on the same layer or adjacent layers

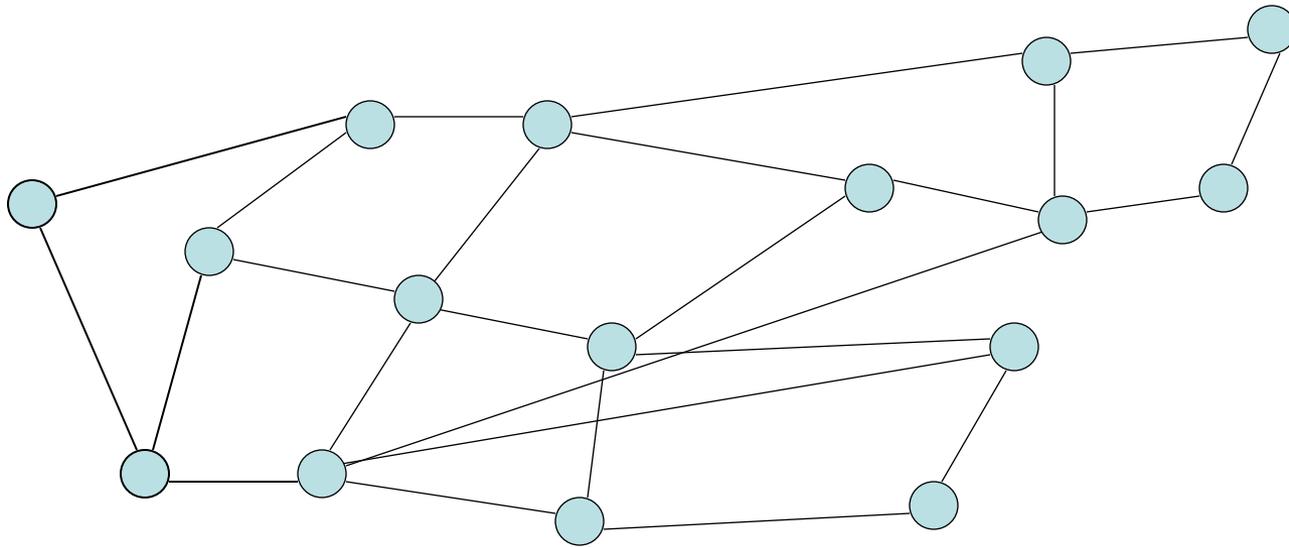

# Bipartite Graphs

- A graph  $V$  is bipartite if  $V$  can be partitioned into  $V_1, V_2$  such that all edges go between  $V_1$  and  $V_2$
- A graph is bipartite if it can be two colored

# Can this graph be two colored?

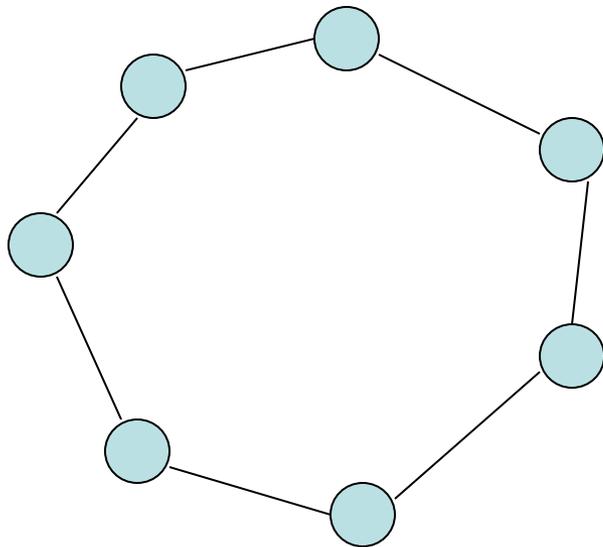

# Algorithm

- Run BFS
- Color odd layers red, even layers blue
- If no edges between the same layer, the graph is bipartite
- If edge between two vertices of the same layer, then there is an odd cycle, and the graph is not bipartite

Theorem: A graph is bipartite if and only if it has no odd cycles

# Lemma 1

- If a graph contains an odd cycle, it is not bipartite

# Lemma 2

- If a BFS tree has an *intra-level edge*, then the graph has an odd length cycle

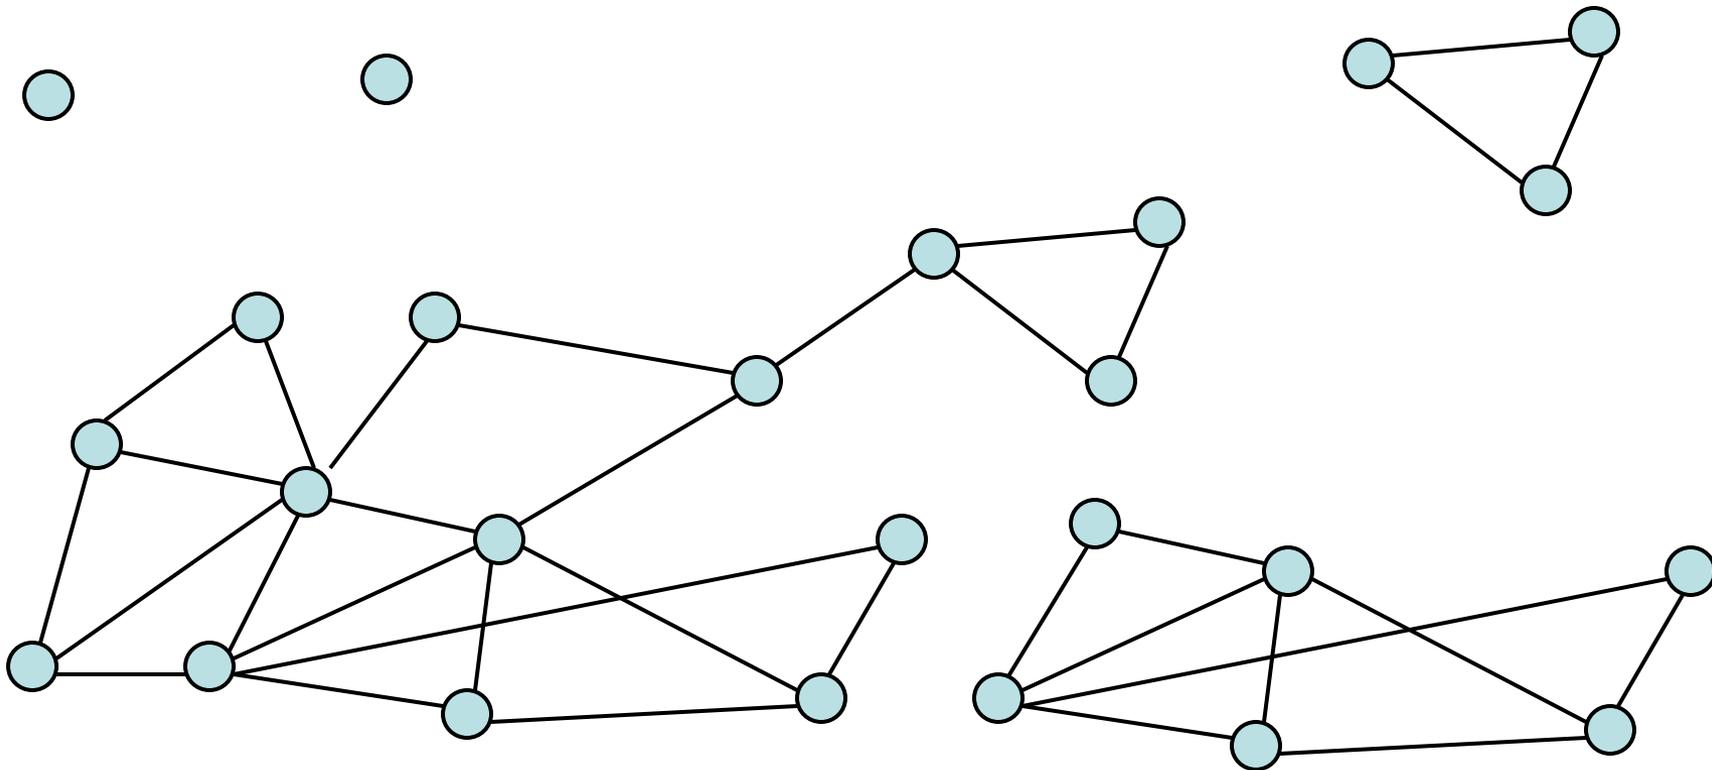

Intra-level edge: both end points are in the same level

# Lemma 3

- If a graph has no odd length cycles, then it is bipartite

# Connected Components

- Undirected Graphs

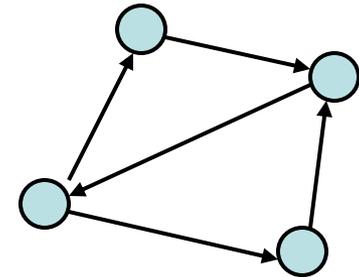

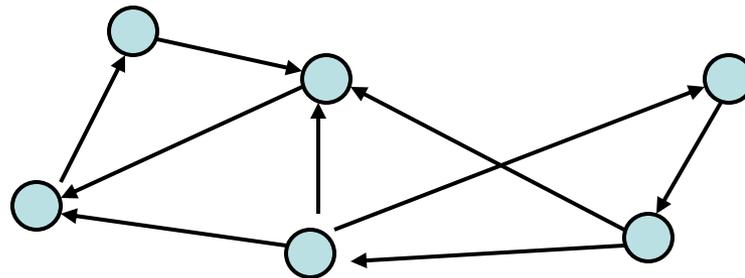

# Computing Connected Components in $O(n+m)$ time

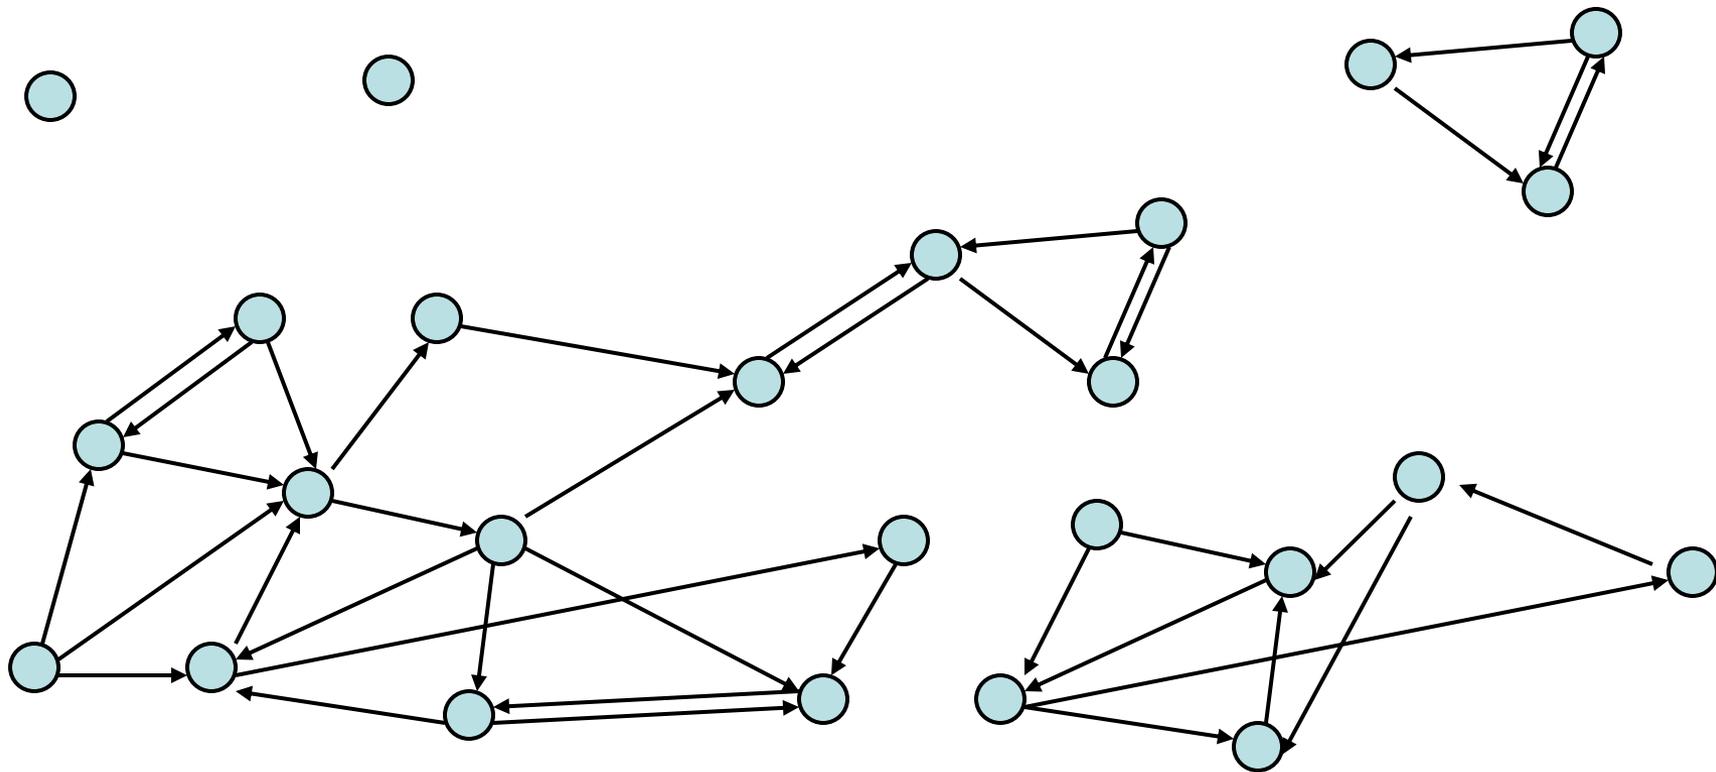

- A search algorithm from a vertex  $v$  can find all vertices in  $v$ 's component
- While there is an unvisited vertex  $v$ , search from  $v$  to find a new component

# Directed Graphs

- A Strongly Connected Component is a subset of the vertices with paths between every pair of vertices.

# Identify the Strongly Connected Components

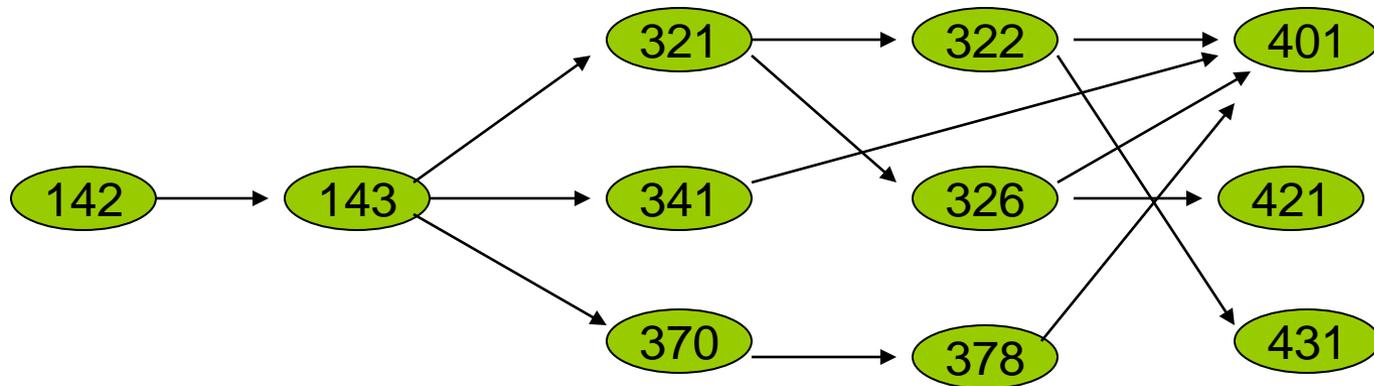

# Strongly connected components can be found in $O(n+m)$ time

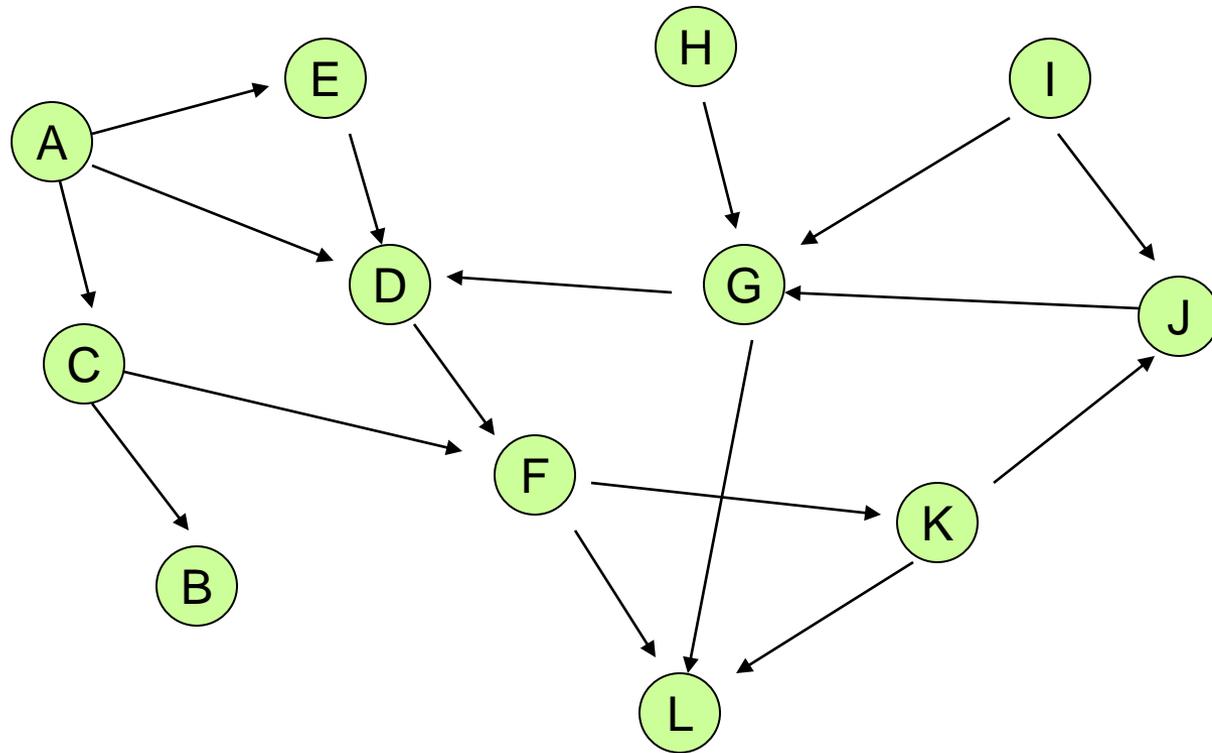

- But it's tricky!
- Simpler problem: given a vertex  $v$ , compute the vertices in  $v$ 's scc in  $O(n+m)$  time

# Topological Sort

- Given a set of tasks with precedence constraints, find a linear order of the tasks

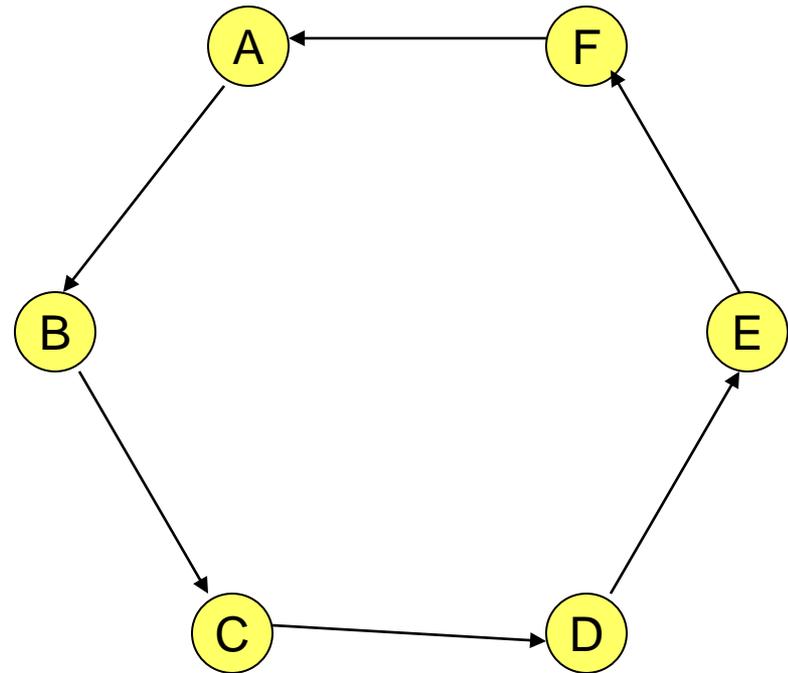

Find a topological order for the following graph

# If a graph has a cycle, there is no topological sort

- Consider the first vertex on the cycle in the topological sort
- It must have an incoming edge

# Lemma: If a graph is acyclic, it has a vertex with in degree 0

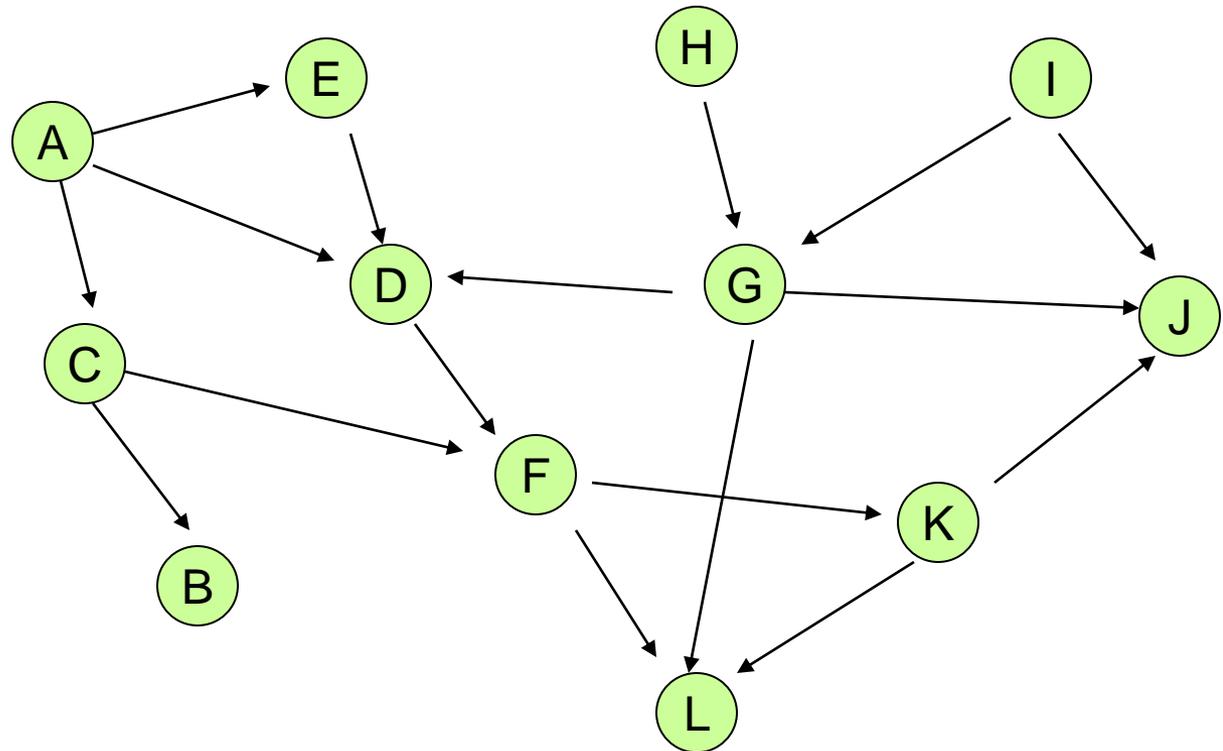

- Proof:
  - Pick a vertex  $v_1$ , if it has in-degree 0 then done
  - If not, let  $(v_2, v_1)$  be an edge, if  $v_2$  has in-degree 0 then done
  - If not, let  $(v_3, v_2)$  be an edge . . .
  - If this process continues for more than  $n$  steps, we have a repeated vertex, so we have a cycle

# Topological Sort Algorithm

While there exists a vertex  $v$  with in-degree 0

Output vertex  $v$

Delete the vertex  $v$  and all out going edges

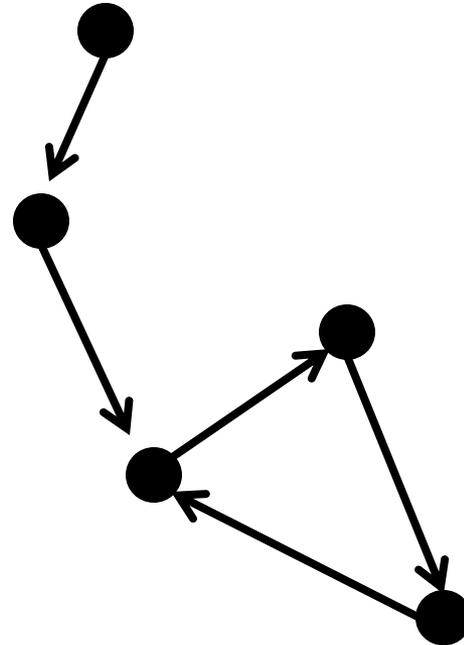

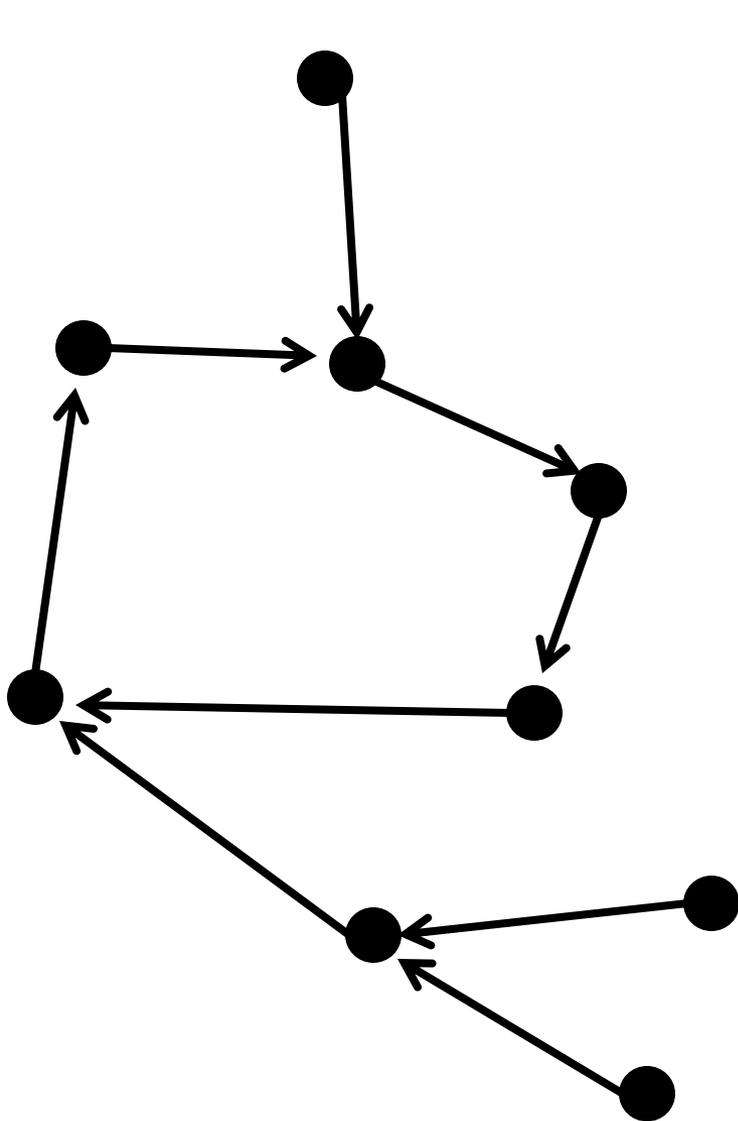

# Details for $O(n+m)$ implementation

- Maintain a list of vertices of in-degree 0
- Each vertex keeps track of its in-degree
- Update in-degrees and list when edges are removed
- $m$  edge removals at  $O(1)$  cost each

# Random Graph models

# Random out degree one graph

Question:  
What is the cycle structure as  $N$  gets large?  
How many cycles?  
What is the cycle length?

# Greedy Algorithms

MATT GROENING

# Greedy Algorithms

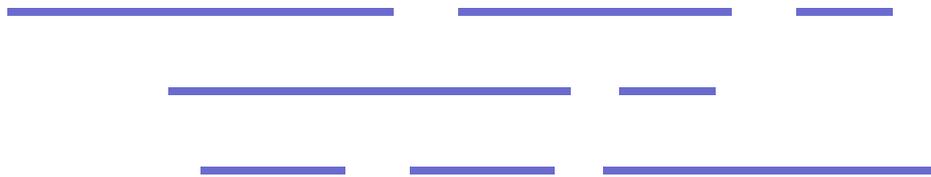

- Solve problems with the simplest possible algorithm
- The hard part: showing that something simple actually works
- Pseudo-definition
  - An algorithm is **Greedy** if it builds its solution by adding elements one at a time using a simple rule

# Scheduling Theory

- Tasks
  - Processing requirements, release times, deadlines
- Processors
- Precedence constraints
- Objective function
  - Jobs scheduled, lateness, total execution time

# Interval Scheduling

- Tasks occur at fixed times
- Single processor
- Maximize number of tasks completed

- Tasks  $\{1, 2, \dots, N\}$
- Start and finish times,  $s(i)$ ,  $f(i)$

# Greedy Algorithm for Scheduling

Let  $T$  be the set of tasks, construct a set of independent tasks  $I$ ,  $A$  is the rule determining the greedy algorithm

$I = \{ \}$

While ( $T$  is not empty)

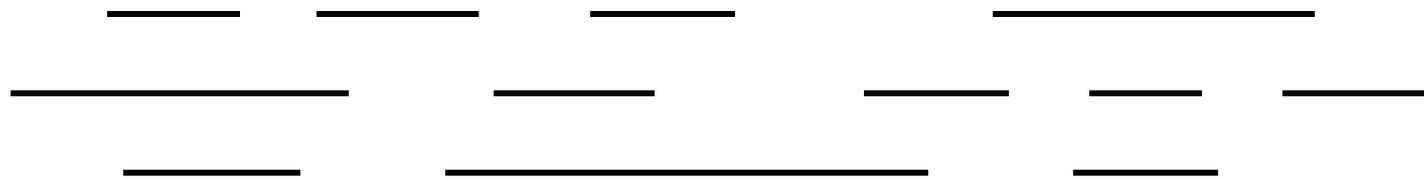

    Select a task  $t$  from  $T$  by a rule  $A$

    Add  $t$  to  $I$

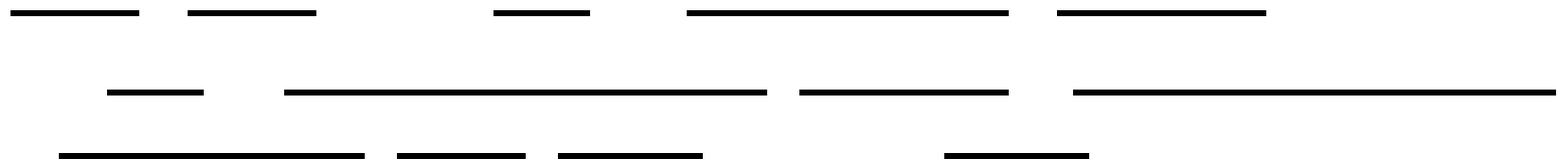

    Remove  $t$  and all tasks incompatible with  $t$  from  $T$

# Simulate the greedy algorithm for each of these heuristics

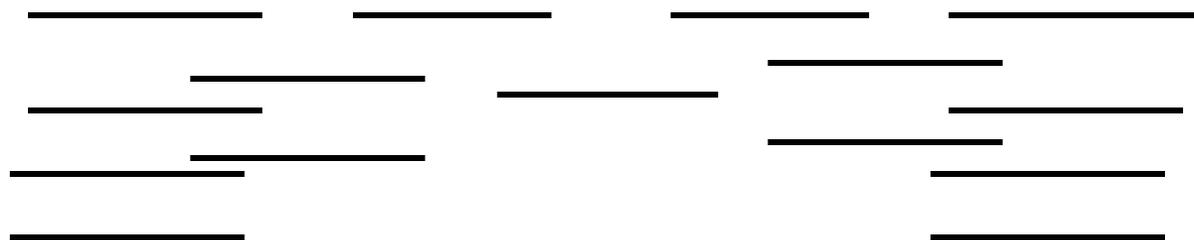

Schedule earliest starting task

Schedule shortest available task

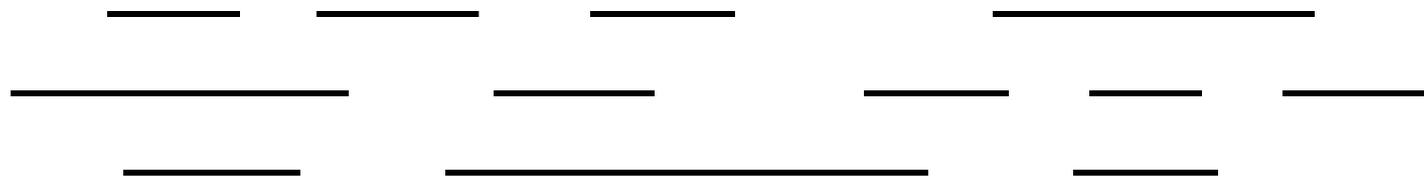

Schedule task with fewest conflicting tasks

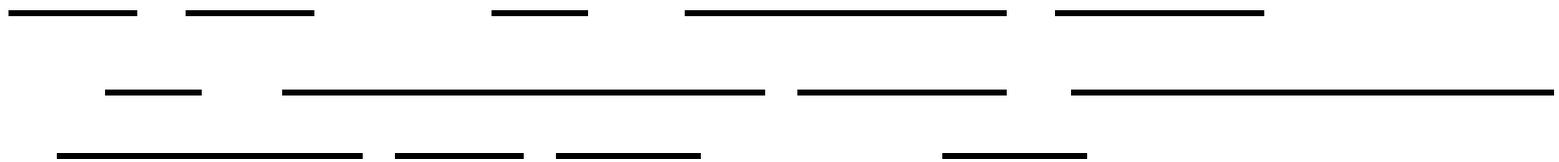

# Greedy solution based on earliest finishing time

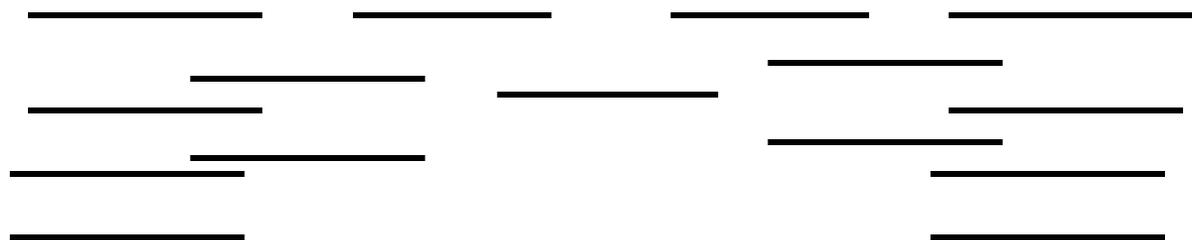

Example 1

Example 2

Example 3

# Theorem: Earliest Finish Algorithm is Optimal

- Key idea: Earliest Finish Algorithm stays ahead
- Let  $A = \{i_1, \dots, i_k\}$  be the set of tasks found by EFA in increasing order of finish times
- Let  $B = \{j_1, \dots, j_m\}$  be the set of tasks found by a different algorithm in increasing order of finish times
- Show that for  $r \leq \min(k, m)$ ,  $f(i_r) \leq f(j_r)$

# Stay ahead lemma

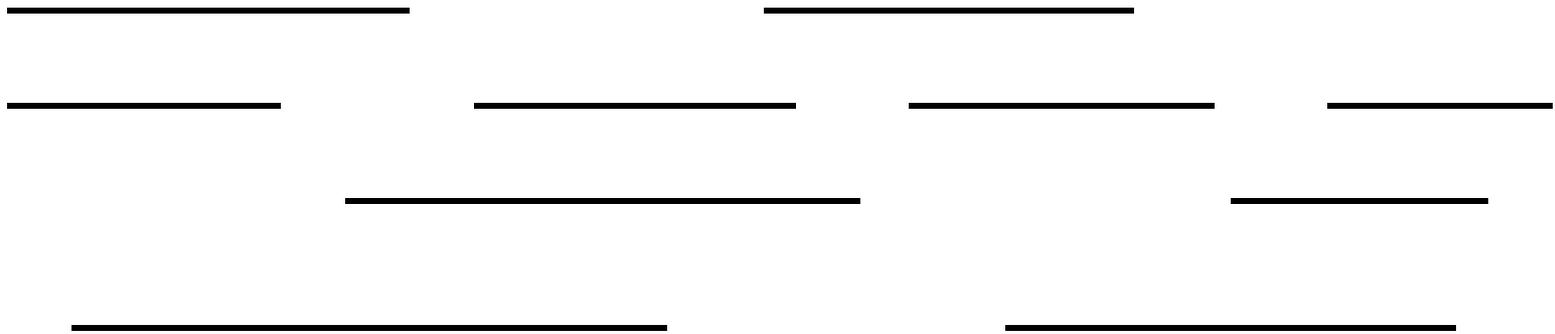

- A always stays ahead of B,  $f(i_r) \leq f(j_r)$
- Induction argument
  - $f(i_1) \leq f(j_1)$
  - If  $f(i_{r-1}) \leq f(j_{r-1})$  then  $f(i_r) \leq f(j_r)$

# Completing the proof

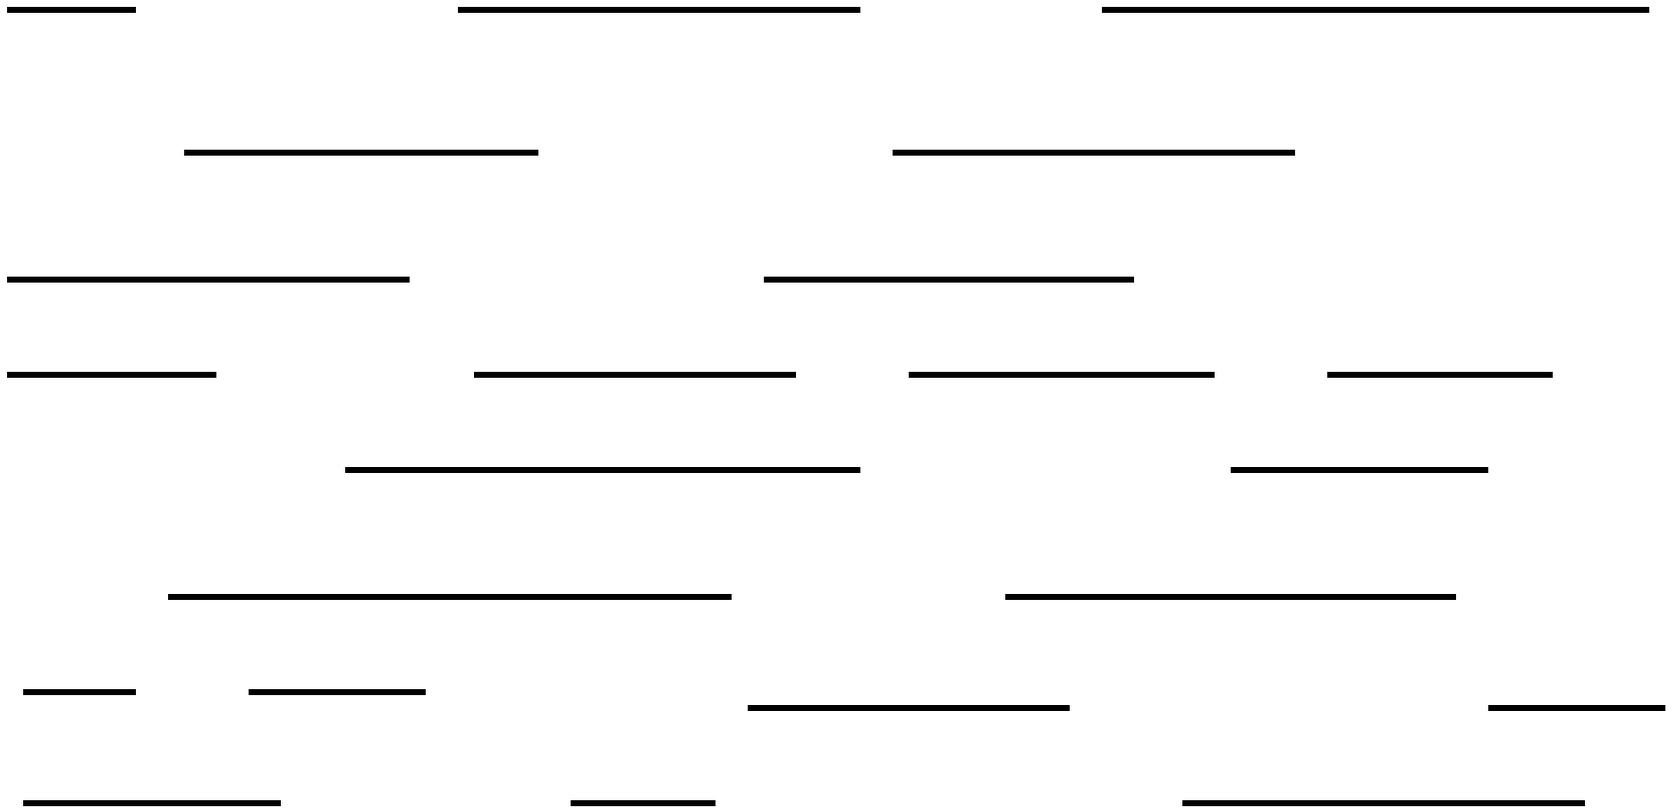

- Let  $A = \{i_1, \dots, i_k\}$  be the set of tasks found by EFA in increasing order of finish times
- Let  $O = \{j_1, \dots, j_m\}$  be the set of tasks found by an optimal algorithm in increasing order of finish times
- If  $k < m$ , then the Earliest Finish Algorithm stopped before it ran out of tasks

# Scheduling all intervals

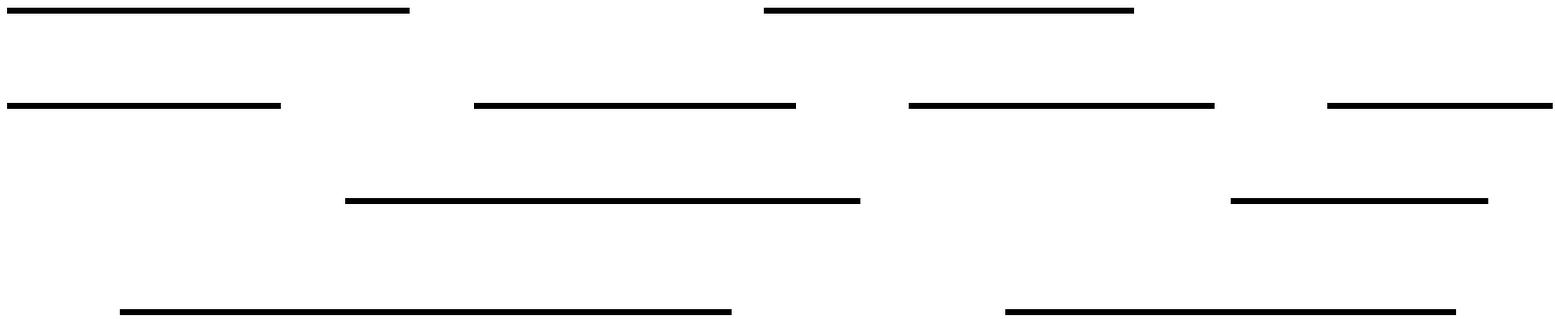

- Minimize number of processors to schedule all intervals

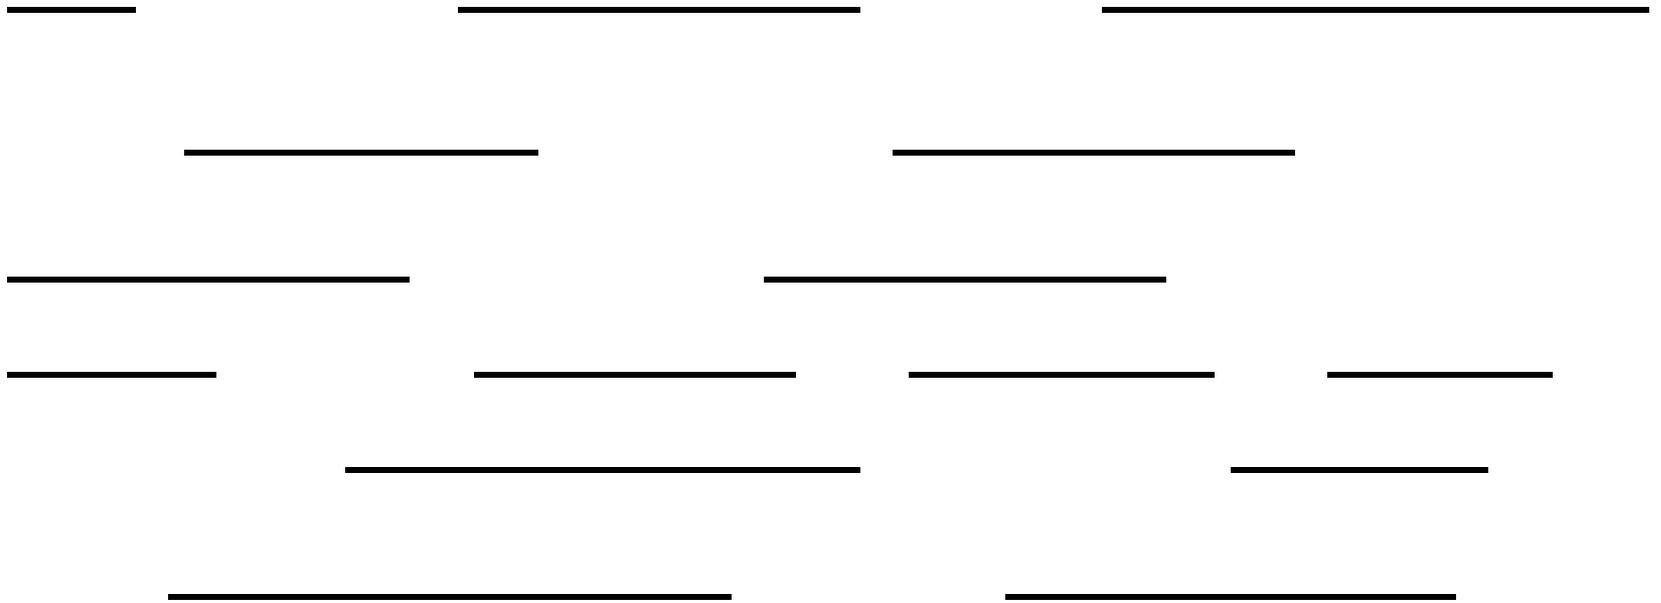

How many processors are needed  
for this example?

Prove that you cannot schedule this set of intervals with two processors

Depth: maximum number of intervals active

# Algorithm

- Sort by start times
- Suppose maximum depth is  $d$ , create  $d$  slots
- Schedule items in increasing order, assign each item to an open slot
- Correctness proof: When we reach an item, we always have an open slot

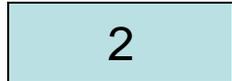

# Scheduling tasks

- Each task has a length  $t_i$  and a deadline  $d_i$
- All tasks are available at the start
- One task may be worked on at a time
- All tasks must be completed
  
- Goal minimize maximum lateness
  - Lateness =  $f_i - d_i$  if  $f_i \geq d_i$

# Example

Time

Deadline

2

4

Lateness 1

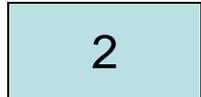

Lateness 3

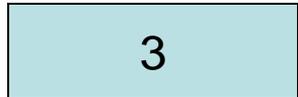

# Determine the minimum lateness

Time

Deadline

6

4

5

12

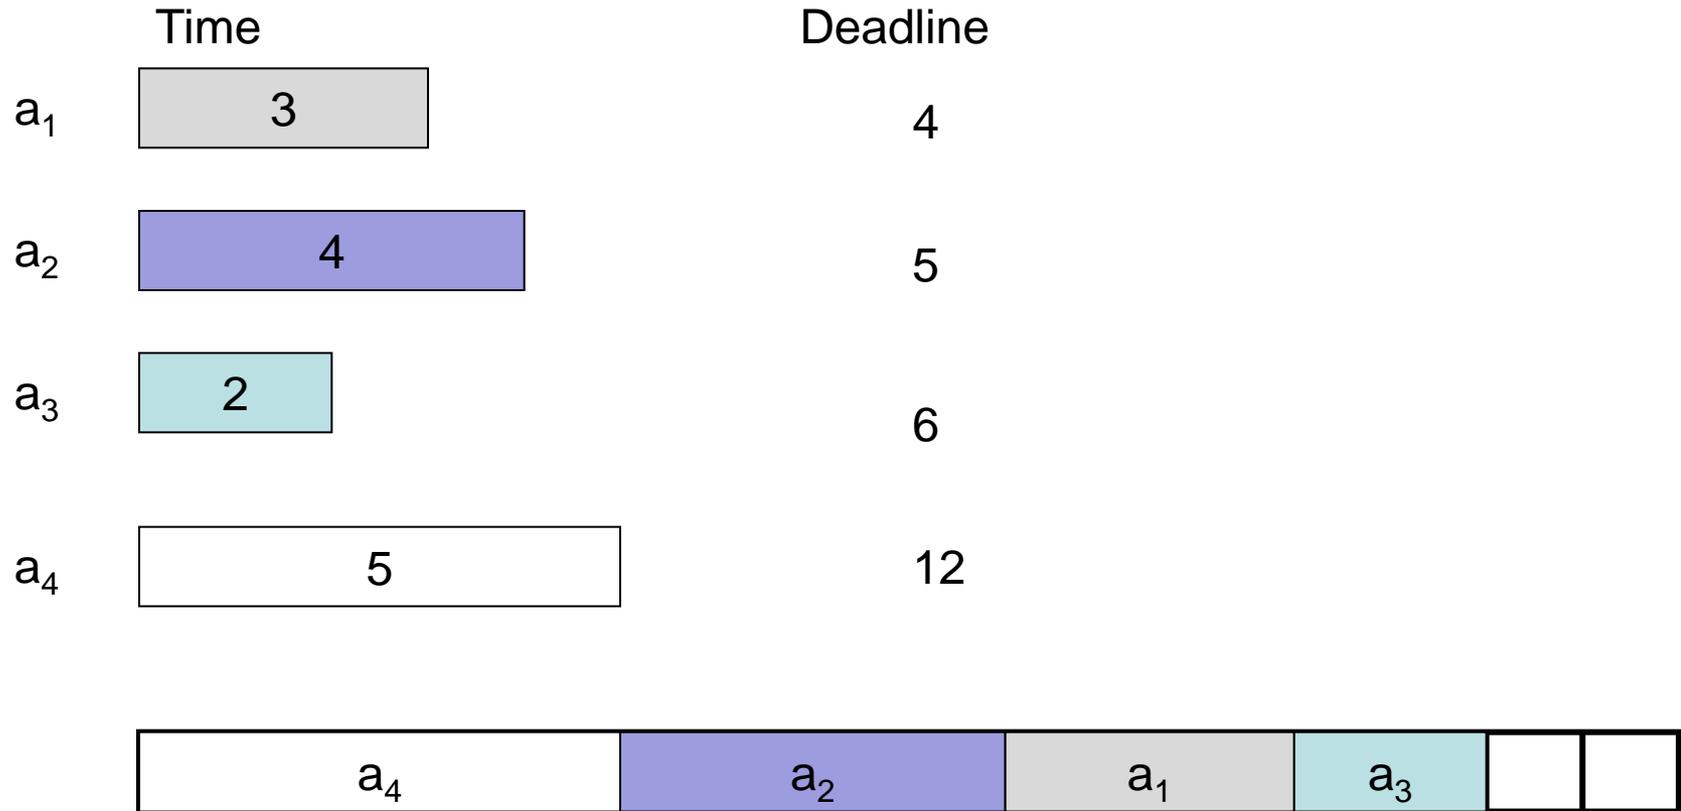

# Greedy Algorithm

- Earliest deadline first
- Order jobs by deadline
- This algorithm is optimal

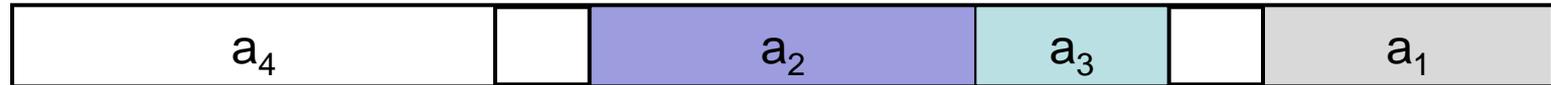

# Analysis

- Suppose the jobs are ordered by deadlines,  $d_1 \leq d_2 \leq \dots \leq d_n$
- A schedule has an *inversion* if job  $j$  is scheduled before  $i$  where  $j > i$
- The schedule  $A$  computed by the greedy algorithm has no inversions.
- Let  $O$  be the optimal schedule, we want to show that  $A$  has the same maximum lateness as  $O$

# List the inversions

# Lemma: There is an optimal schedule with no idle time

- It doesn't hurt to start your homework early!
- Note on proof techniques
  - This type of can be important for keeping proofs clean
  - It allows us to make a simplifying assumption for the remainder of the proof

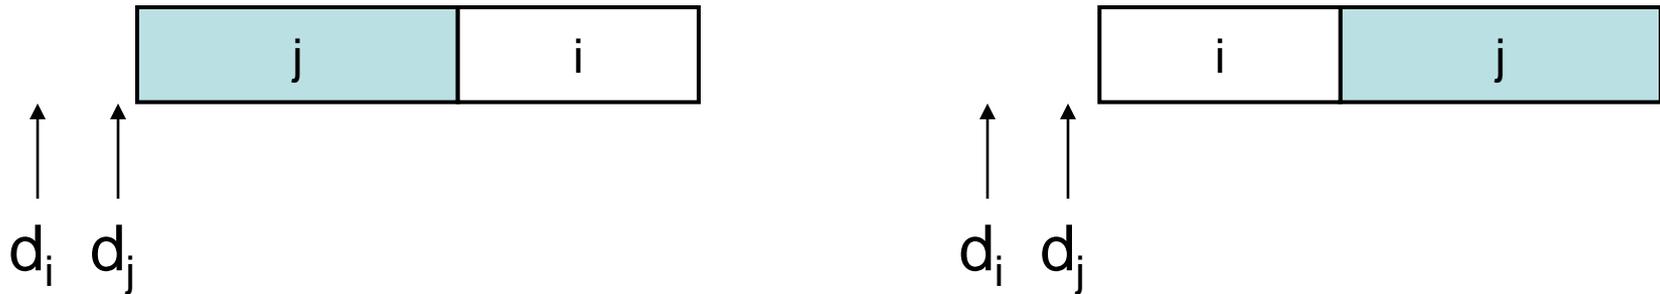

# Lemma

- If there is an inversion  $i, j$ , there is a pair of adjacent jobs  $i', j'$  which form an inversion

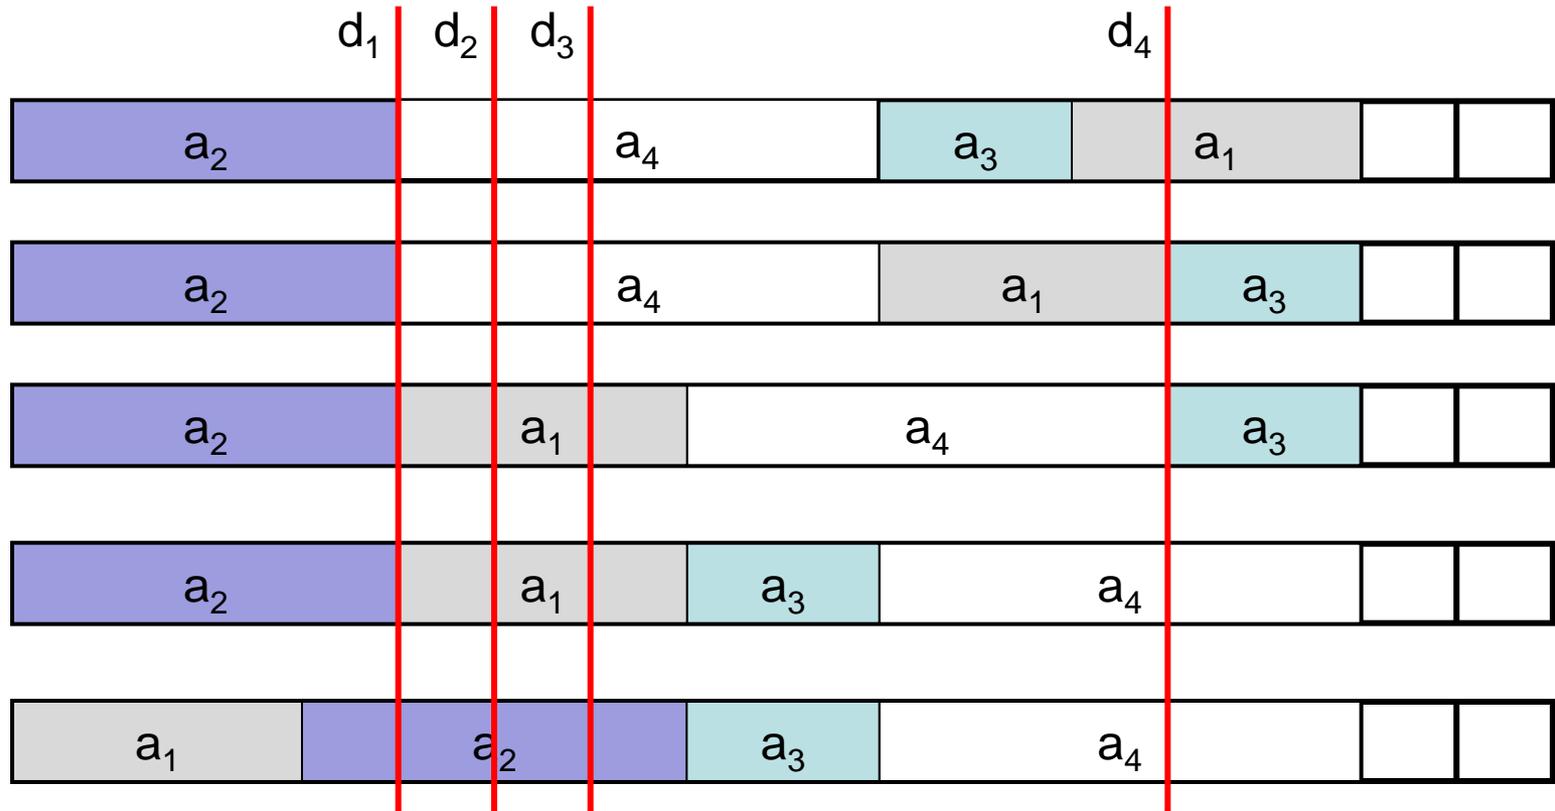

# Interchange argument

- Suppose there is a pair of jobs  $i$  and  $j$ , with  $d_i \leq d_j$ , and  $j$  scheduled immediately before  $i$ . Interchanging  $i$  and  $j$  does not increase the maximum lateness.

# Proof by Bubble Sort

Determine maximum lateness

# Real Proof

- There is an optimal schedule with no inversions and no idle time.
- Let  $O$  be an optimal schedule  $k$  inversions, we construct a new optimal schedule with  $k-1$  inversions
- Repeat until we have an optimal schedule with 0 inversions
- This is the solution found by the earliest deadline first algorithm

# Result

- Earliest Deadline First algorithm constructs a schedule that minimizes the maximum lateness

# Homework Scheduling

- How is the model unrealistic?

# Extensions

- What if the objective is to minimize the sum of the lateness?
  - EDF does not seem to work
- If the tasks have release times and deadlines, and are non-preemptable, the problem is NP-complete
- What about the case with release times and deadlines where tasks are preemptable?
