Geometric optics

Modern theories of light treat it as both a wave and a particle.

We will take a combined and somewhat simpler view of light — the view of geometric optics.

Here are the rules of geometric optics:

- Light is a flow of photons with wavelengths. We'll call these flows "light rays."
- Light rays travel in straight lines in free space.
- Light rays do not interfere with each other as they cross.
- Light rays obey the laws of reflection and refraction.
- Light rays travel from the light sources to the eye, but the physics is invariant under path reversal (reciprocity).

Eye vs. light ray tracing

Where does light begin?

At the light: light ray tracing (a.k.a., forward ray tracing or photon tracing)

At the eye: eye ray tracing (a.k.a., backward ray tracing)

We will generally follow rays from the eye into the scene.

Reading

Required:

- Marschner and Shirley, Ch. 4, Section 13.1-13.2 (online handout)
- Triangle intersection (online handout)

Further reading:

- Shirley errata on syllabus page, needed if you work from his book instead of the handout, which has already been corrected.
Precursors to ray tracing

Local illumination
- Cast one eye ray, then shade according to light

Appel (1968)
- Cast one eye ray + one ray to light

Whitted ray-tracing algorithm

In 1980, Turner Whitted introduced ray tracing to the graphics community:
- Combines eye ray tracing + rays to light
- Recursively traces rays

Algorithm:
1. For each pixel, trace a primary ray in direction \( V \) to the first visible surface.
2. For each intersection, trace secondary rays:
   - Shadow rays in directions \( L_i \) to light sources
   - Reflected ray in direction \( R \)
   - Refracted ray or transmitted ray in direction \( T \)

Whitted algorithm (cont'd)

Let's look at this in stages:

- Primary rays
- Shadow rays
- Reflection rays
- Refracted rays

Ray casting and local illumination

Now let's actually build the ray tracer in stages. We'll start with ray casting and local illumination:
Direct illumination

A ray is defined by an origin $P$ and a unit direction $d$ and is parameterized by $t > 0$:

$$r(t) = P + t d$$

Let $I(P, d)$ be the intensity seen along a ray. Then:

$$I(P, d) = I_{\text{direct}}$$

Shading pseudocode

Next, we need to calculate the color returned by the $shade$ function.

```
function shade (mtrl, scene, Q, N, d):
    I ← mtrl.$k_e$
    for each light source Light do:
        atten = Light -> distanceAttenuation ( Q )
        L = Light -> getDirection ( Q )
        I ← I + ambient + atten*(diffuse + specular)
    end for
    return I
end function
```

Ray-tracing pseudocode

We build a ray traced image by casting rays through each of the pixels.

```
function traceImage (scene):
    for each pixel $(i, j)$ in image
        $A = \text{pixelToWorld}(i, j)$
        $P = C$
        $d = (A - P) \cdot (A - P)$
        $I_{(i,j)} = \text{traceRay} (\text{scene}, P, d)$
    end for
end function
```

```
function traceRay (scene, P, d):
    $(t, N, mtrl) ← \text{scene}.\text{intersect} (P, d)$
    $Q ← \text{ray} (P, d)$ evaluated at $t$
    $I = \text{shade} (N, mtrl, scene, Q)$
    return $I$
end function
```

Ray casting with shadows

Now we’ll add shadows by casting shadow rays:
Shading with shadows

To include shadows, we need to modify the shade function:

```python
def shade(mtrl, scene, Q, N, d):
    I = mtrl.ambient * k
    for each light source Light do:
        atten = Light.distanceAttenuation(Q) * Light.shadowAttenuation(Q)
        L = Light.getDirection(Q)
        I = I + ambient + atten*(diffuse + specular)
    end for
    return I
end function
```

Shading in “Trace”

The Trace project uses a version of the Blinn-Phong shading equation we derived in class, with two modifications:

- Distance attenuation is clamped to be at most 1:
  \[ A_{dist}^i = \min \left\{ 1, \frac{1}{a_j f_j^i + b_j c_i + c_i} \right\} \]

- Shadow attenuation \( A_{shadow} \) is included and is RGB-valued.

Here’s what the shading equation should look like:

\[
I = k_i + \sum_j k_j I_{a,j} + A_{shadow} A_{dist}^i I_{a,j} R \left[ k_i (N \cdot L_j) + k_s (N \cdot H_j) \right]
\]

This is the shading equation to use in the Trace project!

Shadow attenuation

Computing a shadow can be as simple as checking to see if a ray makes it to the light source.

For a point light source:

```python
def PointLight::shadowAttenuation(scene, Q):
    L = getDirection(Q) - scene.intersect(Q, L)
    if \( t_c < t_{light} \):
        atten = (0, 0, 0)
    else:
        atten = (1, 1, 1)
    return atten
end function
```

Note: we will later handle color-filtered shadowing, so this function needs to return a color value.

For a directional light, \( t_{light} = \infty \).

Recursive ray tracing with reflection

Now we’ll add reflection:
Shading with reflection

Let $I(P, d)$ be the intensity seen along a ray. Then:

$$I(P, d) = I_{direct} + I_{reflected}$$

where

- $I_{direct}$ is computed from the Blinn-Phong model, plus shadow attenuation
- $I_{reflected} = k_s I(Q, R)$

Remember that $I$ is a color value.

(Sometimes another variable, $k_r$, is used instead of $k_s$ to allow for separate control of specular light reflection vs specular interreflection. We will not do this.)

Ray-tracing pseudocode, revisited

```plaintext
function traceRay(scene, P, d):
    t, N, mtrl ← scene.intersect(P, d)
    Q ← ray(P, d) evaluated at $t$
    I = shade(scene, mtrl, Q, N, d)
    R = reflectDirection(N, d)
    I ← I + mtrl.$k_s$ * traceRay(scene, Q, R)
    return I
end function
```

Terminating recursion

Q: How do you bottom out of recursive ray tracing?

Possibilities:
**Whitted ray tracing**

Finally, we’ll add refraction, giving us the Whitted ray tracing model:

**Refraction**

Snell’s law of refraction:

\[ \eta_i \sin \theta_i = \eta_t \sin \theta_t \]

where \( \eta_i, \eta_t \) are indices of refraction.

In all cases, \( R \) and \( T \) are co-planar with \( d \) and \( N \).

The index of refraction is material dependent.

It can also vary with wavelength, an effect called dispersion that explains the colorful light rainbows from prisms. (We will generally assume no dispersion.)

<table>
<thead>
<tr>
<th>Medium</th>
<th>Index of refraction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vacuum</td>
<td>1</td>
</tr>
<tr>
<td>Air</td>
<td>1.0003</td>
</tr>
<tr>
<td>Water</td>
<td>1.33</td>
</tr>
<tr>
<td>Fused quartz</td>
<td>1.46</td>
</tr>
<tr>
<td>Glass, crown</td>
<td>1.52</td>
</tr>
<tr>
<td>Glass, dense flint</td>
<td>1.66</td>
</tr>
<tr>
<td>Diamond</td>
<td>2.42</td>
</tr>
</tbody>
</table>

Refraction variation for fused quartz

**Total Internal Reflection**

The equation for the angle of refraction can be computed from Snell’s law:

\[ \eta_i \sin \theta_i = \eta_t \sin \theta_t \]

\[ \theta_i = \sin^{-1} \left( \frac{\eta_i}{\eta_t} \sin \theta_t \right) \]

What “bad thing” can happen when \( \eta_i > \eta_t \)?

When \( \theta_i \) is exactly 90°, we say that \( \theta_i \) has achieved the “critical angle” \( \theta_c \).

For \( \theta_i > \theta_c \), no rays are transmitted, and only reflection occurs, a phenomenon known as “total internal reflection” or TIR.

**Shading with reflection and refraction**

Let \( R(P, d) \) be the intensity seen along a ray. Then:

\[ R(P, d) = I_{\text{direct}} + I_{\text{reflected}} + I_{\text{transmitted}} \]

where

- \( I_{\text{direct}} \) is computed from the Blinn-Phong model, plus shadow attenuation
- \( I_{\text{reflected}} = k_s R(Q, R) \)
- \( I_{\text{transmitted}} = k_t R(Q, T) \)

Typically, we set \( k_t = 1 - k_s \) (or \((0,0,0)\), if opaque, where \( k_s \) is a color value).

[Generally, for ideal specular surfaces, \( k_s \) and \( k_t \) are determined by “Fresnel reflection,” which depends on angle of incidence and changes the polarization of the light. This is discussed in Marschner’s textbook and can be implemented for extra credit.]
Marschner’s notation

Marschner uses different symbols. Here is the translation between them:

\[
\begin{align*}
    r &= R \\
    t &= T \\
    \phi &= \theta \\
    \phi &= \theta_i = \theta_t \\
    n &= n_i \\
    n_i &= n_t
\end{align*}
\]

Ray-tracing pseudocode, revisited

function traceRay (scene, P, d):

\[
\begin{align*}
    (t, N, mtrl) &\leftarrow \text{scene.intersect}(P, d) \\
    Q &\leftarrow \text{ray}(P, d) \text{ evaluated at } t \\
    I &\leftarrow \text{shade}(\text{scene}, \text{mtrl}, Q, N, d) \\
    R &\leftarrow \text{reflectDirection}(N, d) \\
    I &\leftarrow I + \text{mtrl}.k_s \times \text{traceRay}(\text{scene}, Q, R)
\end{align*}
\]

if ray is entering object then

\[
\begin{align*}
    n_i &= \text{index of air (}=1.0003) \\
    n_t &= \text{mtrl.index}
\end{align*}
\]

else

\[
\begin{align*}
    n_i &= \text{mtrl.index} \\
    n_t &= \text{index of air (}=1.0003)
\end{align*}
\]

if \( \text{notTIR}(\Delta) \) then

\[
\begin{align*}
    T &\leftarrow \text{refractDirection}(\Delta) \\
    I &\leftarrow I + \text{mtrl}.k_t \times \text{traceRay}(\text{scene}, Q, T)
\end{align*}
\]

end if

return \( I \)
end function

Q: How do we decide if a ray is entering the object?

Terminating recursion, incl. refraction

Q: How do we bottom out of recursive ray tracing?

Do this

Max depth cut off

Extra credit

Shadow attenuation (cont’d)

Q: What if there are transparent objects along a path to the light source?

We’ll take the view that the color is really only at the surface, like a glass object with a colored transparency coating on it. In this case, we multiply in the transparency constant, \( k_t \), every time an object is entered or exited, possibly more than once for the same object.
Shadow attenuation (cont’d)

Another model would be to treat the glass as solidly colored in the interior. Marschner’s textbook describes a resulting volumetric attenuation based on Beer’s Law, which you can implement for extra credit.

Photon mapping

Combine light ray tracing (photon tracing) and eye ray tracing:

…to get photon mapping.

Renderings by Henrik Wann Jensen:
http://graphics.ucsd.edu/~henrik/images/caustics.html

Normals and shading, reflection, and refraction when inside

When a ray is inside an object and intersects the object’s surface on the way out, the normal will be pointing away from the ray (i.e., the normal always points to the outside by default).

You must negate the normal before doing any of the shading, reflection, and refraction that follows.

Finally, when shading a point inside of an object, apply $k_t$ to the ambient component, since that “ambient light” had to pass through the object to get there in the first place.

Intersecting rays with spheres

Now we’ve done everything except figure out what that "scene.intersect($P, d$)" function does.

Mostly, it calls each object to find out the $t$-value at which the ray intersects the object. Let’s start with intersecting spheres…

Given:

- The coordinates of a point along a ray passing through $P$ in the direction $d$ are:
  
  \[
  x = P_x + td_x \\
  y = P_y + td_y \\
  z = P_z + td_z
  \]

- A sphere $S$ of radius $r$ centered at the origin defined by the equation:

  \[
  x^2 + y^2 + z^2 = r^2
  \]

Find: The $t$ at which the ray intersects $S$.
Intersecting rays with spheres

Solution by substitution:

\[ x^2 + y^2 + z^2 - r^2 = 0 \]
\[ (P_x + t, d_x)^2 + (P_y + t, d_y)^2 + (P_z + t, d_z)^2 - r^2 = 0 \]
\[ at^2 + bt + c = 0 \]

where

\[ a = d_x^2 + d_y^2 + d_z^2 \]
\[ b = 2(P_x d_x + P_y d_y + P_z d_z) \]
\[ c = P_x^2 + P_y^2 + P_z^2 - r^2 \]

Q: What are the solutions of the quadratic equation in \( t \) and what do they mean?

\[ t = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]

\[ \Delta = b^2 - 4ac \]

\[ \Delta < 0 \Rightarrow 2 \text{ complex conjugate roots} \]

Q: What is the normal to the sphere at a point \((x, y, z)\) on the sphere?

\[ \hat{n} = \left( \frac{x, y, z}{\sqrt{x^2 + y^2 + z^2}} \right) \]

Note: the Trace project only requires you to handle a sphere of radius \( r = 0.5 \). This sphere may be arbitrarily transformed when placed in the scene, but everything works out in the end. More later!

Ray-plane intersection

Next, we will considering intersecting a ray with a plane.

To do this, we first need to define the plane equation.

Given a point \( S \) on a plane with normal \( N \), how would we determine if another point \( X \) is on the plane?

(Hint: start by forming the vector \( X - S \).)

This is the plane equation!

Ray-triangle intersection

To intersect with a triangle, we first solve for the equation of its supporting plane.

How might we compute the (un-normalized) normal?

Given this normal, how would we compute \( k \)?

Using these coefficients, we can intersect the ray with the triangle to solve for \( Q \).

Now, we need to decide if \( Q \) is inside or outside of the triangle…
3D inside-outside test

One way to do this “inside-outside test,” is to see if \( Q \) lies on the left side of each edge as we move counterclockwise around the triangle.

How might we use cross and products to do this?

Barycentric coordinates

As we’ll see in a moment, it is often useful to represent \( Q \) as an affine combination of \( A, B, \) and \( C \):

\[
Q = \alpha A + \beta B + \gamma C
\]

where:

\[
\alpha + \beta + \gamma = 1
\]

We call \( \alpha, \beta, \) and \( \gamma \) the barycentric coordinates of \( Q \) with respect to \( A, B, \) and \( C \).

Computing barycentric coordinates

Given a point \( Q \) that is inside of triangle \( ABC \), we can solve for \( Q \)'s barycentric coordinates in a simple way:

\[
\begin{align*}
\alpha &= \frac{\text{Area}(QBC)}{\text{Area}(ABC)} \\
\beta &= \frac{\text{Area}(AQC)}{\text{Area}(ABC)} \\
\gamma &= \frac{\text{Area}(ABQ)}{\text{Area}(ABC)}
\end{align*}
\]

How can cross products help here?

In the end, these calculations can be performed in the 2D projection as well!

Improvement: project down to 2D first

Without loss of generality, we can make this determination after projecting down a dimension:

If \( Q' \) is inside of \( A'B'C' \), then \( Q \) is inside of \( ABC \).

Why is this projection desirable?  

Which axis should you “project away”?  

(Hint: consider the triangle normal.)
Interpolating vertex properties

The barycentric coordinates can also be used to interpolate vertex properties such as:

- material properties
- texture coordinates
- normals

For example:

\[ k_j(Q) = \alpha k_j(A) + \beta k_j(B) + \gamma k_j(C) \]

Phong interpolated normals

Recall the idea of interpolating normal from the shading lecture, now updated to allow reflection and refraction.

Here’s how it works:

1. Compute normals at the vertices.
2. Interpolate normals and normalize.
3. Shade, reflect, and refract using the interpolated normals.

Interpolated normal in a ray tracer

As before, we will use the interpolated normal for shading, but a problem can arise when using this normal for other ray tracing purposes. Consider:

We see that the interpolated normal \( N_{\text{interp}} \) is of course different from the true geometric (triangle) normal \( N_b \). Here are a couple problems that can arise:

A similar problem can arise for refraction, in which the refracted direction \( T \) is exiting the object, which is also wrong. There is no “right” answer for handling the discrepancy between normal and actual geometry.

Q: How do we interpolate \( N_a, N_b, N_c \) to get \( N \)?

\[ N = \alpha N_a + \beta N_b + \gamma N_c \]

Interpolated normal in a ray tracer, cont’d

We could play it “safe” and always use \( N_b \), but then we will not get nice curved reflections and refractions even when these rays are valid. For Trace, do the following…

Determining when entering/exiting object:

- Use the geometric/true normal \( (N_b) \) when deciding whether you are entering/exiting an object.

Shading:

- Use \( N_{\text{interp}} \) for shading.

Reflection:

1. Start by using \( N_{\text{interp}} \) to compute reflection direction \( R \).
2. If \( R \) is (incorrectly) entering the object, then re-compute \( R \) using \( N_b \).

Refraction:

1. Start by using \( N_{\text{interp}} \) to check for Total Internal Reflection (TIR).
2. If TIR, then do not cast a refracted ray.
3. Else, use \( N_{\text{interp}} \) to compute refraction direction \( T \).
4. If \( T \) is (incorrectly) exiting the object, then use \( N_a \) to re-test for TIR and (if no TIR) to re-compute \( T \).
**Epsilons**

Due to finite precision arithmetic, we do not always get the exact intersection at a surface.

Q: What kinds of problems might this cause?

Q: How might we resolve this?

\[ t < \text{RAY_EPSILON} \Rightarrow \text{no intersection} \]

**Intersecting with xformed geometry**

In general, objects will be placed using transformations. What if the object being intersected were transformed by a matrix \( M \)?

Apply \( M^{-1} \) to the ray first and intersect in object (local) coordinates! **Note**: do not normalize \( d' \! \)

\[
\begin{align*}
M^{-1}\left(Q = P + td\right) \\
M^{-1}Q &= M^{-1}P + M^{-1}(t, d) \\
M^{-1}Q &= M^{-1}P + tN
\end{align*}
\]

\[ t' = P' + tN \]

**Intersecting with xformed geometry**

The intersected normal is in object (local) coordinates. How do we transform it to world coordinates?

\[
\begin{align*}
N &= A^T N' \\
R^T &= R^{-1}
\end{align*}
\]
Summary

What to take home from this lecture:

• The meanings of all the boldfaced terms.
• Enough to implement basic recursive ray tracing.
• How reflection and transmission directions are computed.
• How ray-object intersection tests are performed on spheres, planes, and triangles.
• How barycentric coordinates within triangles are computed.
• How ray epsilons are used.
