

Projections

Reading

Angel. Chapter 5

Optional

David F. Rogers and J. Alan Adams, *Mathematical Elements for Computer Graphics, Second edition*, McGraw-Hill, New York, 1990, Chapter 3.

The 3D synthetic camera model

The **synthetic camera model** involves two components, specified *independently*:

- ◆ objects (a.k.a. **geometry**)
- ◆ viewer (a.k.a. **camera**)

Imaging with the synthetic camera

The image is rendered onto an **image plane** or **projection plane** (usually in front of the camera).

Projectors emanate from the **center of projection** (COP) at the center of the lens (or pinhole).

The image of an object point P is at the intersection of the projector through P and the image plane.

Specifying a viewer

Camera specification requires four kinds of parameters:

- ◆ *Position*: the COP.
- ◆ *Orientation*: rotations about axes with origin at the COP.
- ◆ *Focal length*: determines the size of the image on the film plane, or the **field of view**.
- ◆ *Film plane*: its width and height, and possibly orientation.

Projections

Projections transform points in n -space to m -space, where $m < n$.

In 3D, we map points from 3-space to the **projection plane (PP)** along **projectors** emanating from the **center of projection (COP)**.

There are two basic types of projections:

- ◆ **Perspective** - distance from COP to PP finite
- ◆ **Parallel** - distance from COP to PP infinite

Parallel and Perspective Projection

Perspective vs. parallel projections

Perspective projections pros and cons:

- + Size varies inversely with distance - looks realistic
- Distance and angles are not (in general) preserved
- Parallel lines do not (in general) remain parallel

Parallel projection pros and cons:

- Less realistic looking
- + Good for exact measurements
- + Parallel lines remain parallel
- Angles not (in general) preserved

Parallel projections

For parallel projections, we specify a **direction of projection (DOP)** instead of a COP.

There are two types of parallel projections:

- ◆ **Orthographic projection** — DOP perpendicular to PP
- ◆ **Oblique projection** — DOP not perpendicular to PP

Orthographic Projections

Figure 5.6 Axonometric projections. (a) Construction of trimetric-view projections. (b) Top view. (c) Side view.

Figure 5.7 Axonometric views.

Orthographic transformation

For parallel projections, we specify a **direction of projection** (DOP) instead of a COP.

We can write orthographic projection onto the $z=0$ plane with a simple matrix.

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

Normally, we do not drop the z value right away. Why not?

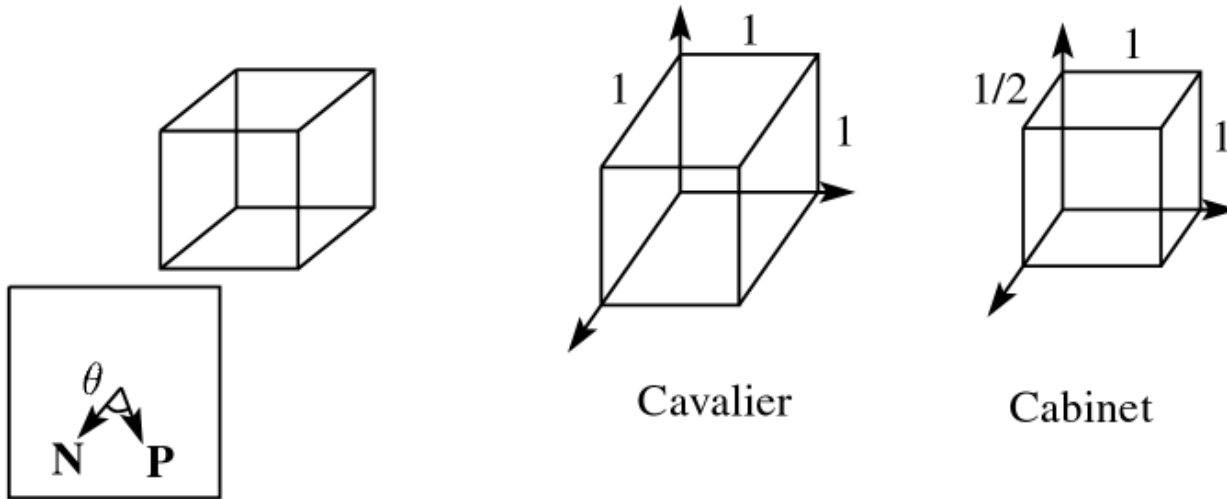

Oblique Projections

Oblique projections

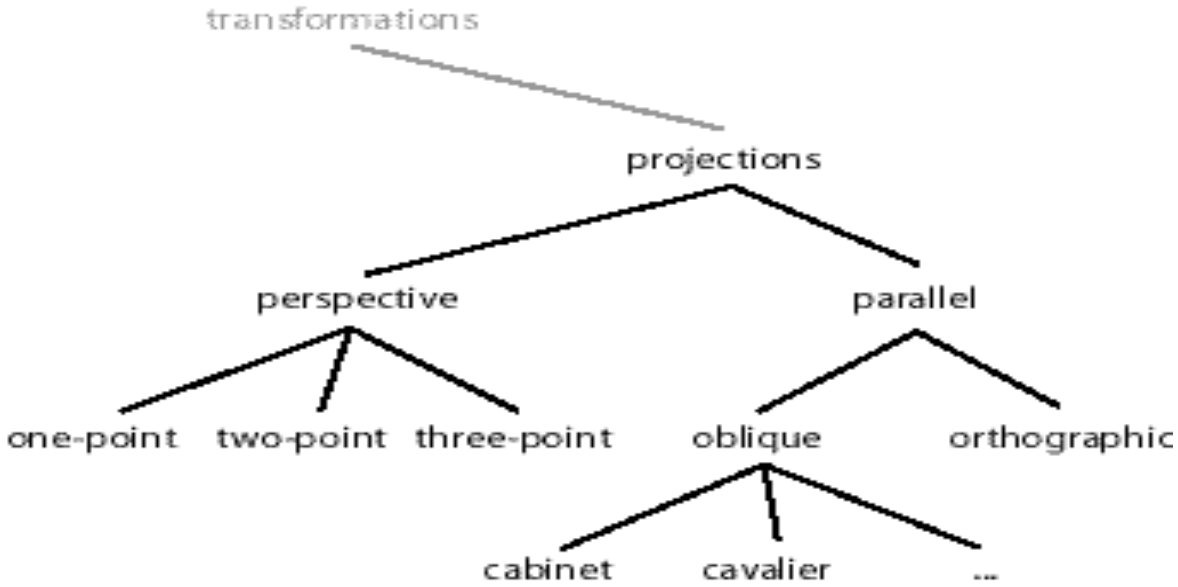

Two standard oblique projections:

- ◆ Cavalier projection
DOP makes 45 angle with PP
Does not foreshorten lines perpendicular to PP
- ◆ Cabinet projection
DOP makes 63.4 angle with PP
Foreshortens lines perpendicular to PP by one-half

Oblique projection geometry

Projection taxonomy

Properties of projections

The perspective projection is an example of a **projective transformation**.

Here are some properties of projective transformations:

- ◆ Lines map to lines
- ◆ Parallel lines *don't* necessarily remain parallel
- ◆ Ratios are *not* preserved

A typical eye space

- ◆ **Eye**
 - Acts as the COP
 - Placed at the origin
 - Looks down the z -axis
- ◆ **Screen**
 - Lies in the PP
 - Perpendicular to z -axis
 - At distance d from the eye
 - Centered on z -axis, with radius s

Q: Which objects are visible?

Eye space \rightarrow screen space

Q: How do we perform the perspective projection from eye space into screen space?

Using similar triangles gives:

Eye space \rightarrow screen space, cont.

We can write this transformation in matrix form:

$$\begin{bmatrix} X \\ Y \\ Z \\ W \end{bmatrix} = MP = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1/d & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = \begin{bmatrix} x \\ y \\ z \\ z/d \end{bmatrix}$$

Perspective divide:

$$\begin{bmatrix} X/W \\ Y/W \\ Z/W \\ W/W \end{bmatrix} = \begin{bmatrix} \frac{x}{z/d} \\ \frac{y}{z/d} \\ \frac{z/d}{d} \\ 1 \end{bmatrix}$$

Projective Normalization

After perspective transformation and perspective divide, we apply parallel projection (drop the z) to get a 2D image.

Perspective depth

Q: What did our perspective projection do to z ?

Often, it's useful to have a z around — e.g., for hidden surface calculations.

Illusions

Vanishing points

Under perspective projections, any set of parallel lines that are not parallel to the PP will converge to a **vanishing point**.

Vanishing points of lines parallel to a principal axis x , y , or z are called **principal vanishing points**.

How many of these can there be?

Vanishing points

The equation for a line is:

$$\mathbf{l} = \mathbf{p} + t\mathbf{v} = \begin{bmatrix} p_x \\ p_y \\ p_z \\ 1 \end{bmatrix} + t \begin{bmatrix} v_x \\ v_y \\ v_z \\ 0 \end{bmatrix}$$

After perspective transformation we get:

$$\begin{bmatrix} x' \\ y' \\ w' \end{bmatrix} = \begin{bmatrix} p_x + tv_x \\ p_y + tv_y \\ -(p_z + tv_z)/d \end{bmatrix}$$

Vanishing points (cont'd)

Dividing by w :

$$\begin{bmatrix} x' \\ y' \\ w' \end{bmatrix} = \begin{bmatrix} -\frac{p_x + tv_x}{p_z + tv_z} d \\ -\frac{p_y + tv_y}{p_z + tv_z} d \\ 1 \end{bmatrix}$$

Letting t go to infinity:

$$\lim_{t \rightarrow \infty} \begin{bmatrix} x' \\ y' \\ w' \end{bmatrix} = \begin{bmatrix} -\frac{v_x}{v_z} d \\ v_z \\ -\frac{v_y}{v_z} d \\ 1 \end{bmatrix}$$

We get a point!

What happens to the line $\mathbf{l} = \mathbf{q} + t\mathbf{v}$?

Each set of parallel lines intersect at a **vanishing point** on the PP.

Q: How many vanishing points are there?

Vanishing Points

One Point Perspective
(z-axis vanishing point)

Three Point Perspective
(z, x, and y-axis
vanishing points)

Two Point Perspective
z, and x-axis vanishing points

Types of perspective drawing

If we define a set of **principal axes** in world coordinates, i.e., the x_w , y_w , and z_w axes, then it's possible to choose the viewpoint such that these axes will converge to different vanishing points.

The vanishing points of the principal axes are called the **principal vanishing points**.

Perspective drawings are often classified by the number of principal vanishing points.

- ◆ One-point perspective — simplest to draw
- ◆ Two-point perspective — gives better impression of depth
- ◆ Three-point perspective — most difficult to draw

All three types are equally simple with computer graphics.

General perspective projection

In general, the matrix

$$\begin{bmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ p & q & r & s \end{bmatrix}$$

performs a perspective projection into the plane $px + qy + rz + s = 1$.

Q: Suppose we have a cube C whose edges are aligned with the principal axes. Which matrices give drawings of C with

- ◆ one-point perspective?
- ◆ two-point perspective?
- ◆ three-point perspective?

General Projections

Suppose you have a camera with COP c , and x , y , and z axes are unit vectors i , j and k respectively. How do we compute the projection?

World Space Camera

Hither and yon planes

In order to preserve depth, we set up two planes:

- ◆ The **hither** (near) plane
- ◆ The **yon** (far) plane

Projection taxonomy

Summary

Here's what you should take home from this lecture:

- ◆ The classification of different types of projections.
- ◆ The concepts of vanishing points and one-, two-, and three-point perspective.
- ◆ An appreciation for the various coordinate systems used in computer graphics.
- ◆ How the perspective transformation works.
