## Recap: Reasoning Over Time

- Markov models

$$
P\left(X_{1}\right) \quad P\left(X \mid X_{-1}\right)
$$

- Hidden Markov models

| $X$ | $E$ | $P$ |
| :---: | :---: | :---: |
| rain | umbrella | 0.9 |
| rain | no umbrella | 0.1 |
| sun | umbrella | 0.2 |
| sun | no umbrella | 0.8 |

## Inference: Find State Given Evidence

- We are given evidence at each time and want to know

$$
B_{t}(X)=P\left(X_{t} \mid e_{1: t}\right)
$$

- Idea: start with $P\left(X_{1}\right)$ and derive $B_{t}$ in terms of $B_{t-1}$
- equivalently, derive $B_{t+1}$ in terms of $B_{t}$

## Inference: Base Cases

## Inference: Base Cases

## Passage of Time

- Assume we have current belief $\mathrm{P}(\mathrm{X} \mid$ evidence to date)

$$
B\left(X_{t}\right)=P\left(X_{t} \mid e_{1: t}\right)
$$

- Then, after one time step passes:

$$
\begin{aligned}
P\left(X_{t+1} \mid e_{1: t}\right) & =\sum_{x_{t}} P\left(X_{t+1}, x_{t} \mid e_{1: t}\right) \\
& =\sum_{x_{t}} P\left(X_{t+1} \mid x_{t}, e_{1: t}\right) P\left(x_{t} \mid e_{1: t}\right) \\
& =\sum_{x_{t}} P\left(X_{t+1} \mid x_{t}\right) P\left(x_{t} \mid e_{1: t}\right)
\end{aligned}
$$

- Or compactly:

$$
B^{\prime}\left(X_{t+1}\right)=\sum_{x_{t}} P\left(X^{\prime} \mid x_{t}\right) B\left(x_{t}\right)
$$

- Basic idea: beliefs get "pushed" through the transitions
- With the " $B$ " notation, we have to be careful about what time step $t$ the belief is about, and what evidence it includes

## Example: Passage of Time

- As time passes, uncertainty "accumulates"

| $<0.01$ | $<0.01$ | $<0.01$ | $<0.01$ | $<0.01$ | $<0.01$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $<0.01$ | $<0.01$ | 0.06 | $<0.01$ | $<0.01$ | $<0.01$ |
| $<0.01$ | 0.76 | 0.06 | 0.06 | $<0.01$ | $<0.01$ |
| $<0.01$ | $<0.01$ | 0.06 | $<0.01$ | $<0.01$ | $<0.01$ |

$$
\mathrm{T}=1
$$

(Transition model: ghosts usually go clockwise)

| 0.05 | 0.01 | 0.05 | $<0.01$ | $<0.01$ | $<0.01$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.02 | 0.14 | 0.11 | 0.35 | $<0.01$ | $<0.01$ |
| 0.07 | 0.03 | 0.05 | $<0.01$ | 0.03 | $<0.01$ |
| 0.03 | 0.03 | $<0.01$ | $<0.01$ | $<0.01$ | $<0.01$ |

## Inference: Base Cases

$$
P\left(X_{1} \mid e_{1}\right)
$$

$$
\begin{aligned}
P\left(x_{1} \mid e_{1}\right) & =P\left(x_{1}, e_{1}\right) / P\left(e_{1}\right) \\
& \propto_{X_{1}} P\left(x_{1}, e_{1}\right) \\
& =P\left(x_{1}\right) P\left(e_{1} \mid x_{1}\right)
\end{aligned}
$$

## Observation

- Assume we have current belief $P(X \mid$ previous evidence $)$ :

$$
B^{\prime}\left(X_{t+1}\right)=P\left(X_{t+1} \mid e_{1: t}\right)
$$

- Then, after evidence comes in:

$$
\begin{aligned}
P\left(X_{t+1} \mid e_{1: t+1}\right) & =P\left(X_{t+1}, e_{t+1} \mid e_{1: t}\right) / P\left(e_{t+1} \mid e_{1: t}\right) \\
& \propto_{X_{t+1}} P\left(X_{t+1}, e_{t+1} \mid e_{1: t}\right) \\
& =P\left(e_{t+1} \mid e_{1: t}, X_{t+1}\right) P\left(X_{t+1} \mid e_{1: t}\right) \\
& =P\left(e_{t+1} \mid X_{t+1}\right) P\left(X_{t+1} \mid e_{1: t}\right)
\end{aligned}
$$

" Basic idea: beliefs "reweighted" by likelihood of evidence

- Or, compactly:

$$
B\left(X_{t+1}\right) \propto_{X_{t+1}} P\left(e_{t+1} \mid X_{t+1}\right) B^{\prime}\left(X_{t+1}\right)
$$

- Unlike passage of time, we have to renormalize

## Example: Observation

- As we get observations, beliefs get reweighted, uncertainty "decreases"

Before observation

After observation

$$
B(X) \propto P(e \mid X) B^{\prime}(X)
$$

## The Forward Algorithm

- We are given evidence at each time and want to know

$$
B_{t}(X)=P\left(X_{t} \mid e_{1: t}\right)
$$

- We can derive the following updates

$$
\begin{aligned}
P\left(x_{t} \mid e_{1: t}\right) & \propto_{X} P\left(x_{t}, e_{1: t}\right) \\
& =\sum_{x_{t-1}} P\left(x_{t-1}, x_{t}, e_{1: t}\right) \\
& =\sum_{x_{t-1}} P\left(x_{t-1}, e_{1: t-1}\right) P\left(x_{t} \mid x_{t-1}\right) P\left(e_{t} \mid x_{t}\right) \\
& =P\left(e_{t} \mid x_{t}\right) \sum_{x_{t-1}} P\left(x_{t} \mid x_{t-1}\right) P\left(x_{t-1}, e_{1: t-1}\right)
\end{aligned}
$$

We can normalize as we go if we want to have $\mathrm{P}(\mathrm{x} \mid e)$ at each time step, or just once at the end...

Filtering: $\mathrm{P}\left(\mathrm{X}_{\mathrm{t}} \mid\right.$ evidence $\left._{1: \mathrm{t}}\right)$

Elapse time: compute $P\left(X_{t} \mid e_{1: t-1}\right)$

$$
P\left(x_{t} \mid e_{1: t-1}\right)=\sum_{x_{t-1}} P\left(x_{t-1} \mid e_{1: t-1}\right) \cdot P\left(x_{t} \mid x_{t-1}\right)
$$

Observe: compute $P\left(X_{t} \mid e_{1: t}\right)$

$$
P\left(x_{t} \mid e_{1: t}\right) \propto P\left(x_{t} \mid e_{1: t-1}\right) \cdot P\left(e_{t} \mid x_{t}\right)
$$

Belief: <P(rain), P(sun)>

$$
P\left(X_{1}\right) \quad<0.5,0.5>\quad \text { Prior on } X_{1}
$$

$$
P\left(X_{1} \mid E_{1}=\text { umbrella }\right) \quad<0.82,0.18>\quad \text { Observe }
$$

$$
P\left(X_{2} \mid E_{1}=\text { umbrella }\right) \quad<0.63,0.37>\quad \text { Elapse time }
$$

$$
P\left(X_{2} \mid E_{1}=u m b, E_{2}=u m b\right) \quad<0.88,0.12>\quad \text { Observe }
$$

## Example: Weather HMM

## Pacman - Sonar (P4)

## Approximate Inference

- Sometimes $|\mathrm{X}|$ is too big for exact inference
- |X| may be too big to even store $\mathrm{B}(\mathrm{X})$
- E.g. when $X$ is continuous
- $|X|^{2}$ may be too big to do updates
- Solution: approximate inference by sampling
- How robot localization works in practice

Approximate Inference: Sampling

## Sampling

- Sampling is a lot like repeated simulation
- Predicting the weather, basketball games, ...
- Basic idea
- Draw N samples from a sampling distribution S
- Compute an approximate probability
- Why sample?
- Learning: get samples from a distribution you don't know
- Inference: getting a sample is faster than computing the right answer

## Sampling

## - Sampling from given distribution

- Step 1: Get sample $u$ from uniform distribution over [0, 1)
- E.g. random() in python
- Step 2: Convert this sample $u$ into an outcome for the given distribution by having each target outcome associated with a sub-interval of $[0,1$ ) with sub-interval size equal to probability of the outcome
- Example

| $C$ | $P(C)$ |
| :---: | :---: |
| red | 0.6 |
| green | 0.1 |
| blue | 0.3 |

$$
\begin{gathered}
0 \leq u<0.6, \rightarrow C=\text { red } \\
0.6 \leq u<0.7, \rightarrow C=\text { green } \\
0.7 \leq u<1, \rightarrow C=\text { blue }
\end{gathered}
$$

- If random() returns $u=0.83$, then our sample is $C=$ blue
- E.g, after sampling 8 times:

## Particle Filtering

## Particle Filtering

- Filtering: approximate solution
- Sometimes $|X|$ is too big to use exact inference
- $|X|$ may be too big to even store $B(X)$
- E.g. $X$ is continuous
- Solution: approximate inference
- Track samples of X, not all values
- Samples are called particles
- Time per step is linear in the number of samples
- But: number needed may be large
- In memory: list of particles, not states
- This is how robot localization works in practice
- Particle is just new name for sample

| 0.0 | 0.1 | 0.0 |
| :--- | :--- | :--- |
| 0.0 | 0.0 | 0.2 |
| 0.0 | 0.2 | 0.5 |
|  |  |  |

## Representation: Particles

- Our representation of $P(X)$ is now a list of $N$ particles (samples)
- Generally, $\mathrm{N} \ll|\mathrm{X}|$
- Storing map from $X$ to counts would defeat the point
- $P(x)$ approximated by number of particles with value $x$

- So, many x may have $P(x)=0$ !
- More particles, more accuracy
- For now, all particles have a weight of 1

## Particle Filtering: Elapse Time

- Each particle is moved by sampling its next position from the transition model

$$
x^{\prime}=\operatorname{sample}\left(P\left(X^{\prime} \mid x\right)\right)
$$

- Samples' frequencies reflect the transition probabilities
- Here, most samples move clockwise, but some move in another direction or stay in place
- This captures the passage of time
- If enough samples, close to exact values before and after (consistent)

## Particle Filtering: Observe

- Slightly trickier:
- Don't sample observation, fix it
- Downweight samples based on the evidence

$$
\begin{aligned}
w(x) & =P(e \mid x) \\
B(X) & \propto P(e \mid X) B^{\prime}(X)
\end{aligned}
$$

- As before, the probabilities don't sum to one, since all have been downweighted (in fact they now sum to ( N times) an approximation of $\mathrm{P}(\mathrm{e})$ )

## Particle Filtering: Resample

- Rather than tracking weighted samples, we resample
- N times, we choose from our weighted sample distribution (i.e. draw with replacement)

(New) Particles:

## Recap: Particle Filtering

- Particles: track samples of states rather than an explicit distribution

$$
x^{\prime}=\operatorname{sample}\left(P\left(X^{\prime} \mid x\right)\right)
$$

$$
w(x)=P(e \mid x)
$$

Video of Demo - Moderate Number of Particles

## Which Algorithm?

Particle filter, uniform initial beliefs, 25 particles

## Which Algorithm?

Exact filter, uniform initial beliefs

## Which Algorithm?

Particle filter, uniform initial beliefs, 300 particles

## Robot Localization

- In robot localization:
- We know the map, but not the robot's position
- Observations may be vectors of range finder readings
- State space and readings are typically continuous (works basically like a very fine grid) and so we cannot store $B(X)$
- Particle filtering is a main technique

## Particle Filter Localization (Sonar)

## Global localization with sonar sensors

## Particle Filter Localization (Laser)
