Software Design & Implementation

James Wilcox

Autumn 2021

Modern Web UIs

Problems

This is better, but it still has problems…

1. Still no checking of HTML (opaque strings)

2. Modularity is still poor
   – need to join strings into one big string

3. More boilerplate
   – minimized JS file would change function names
   – need to call `btn.addEventListener` by hand

JSX

- Fix the first problem by adding HTML as a JS type
- This is supported in `.jsx` files:

```
let x = <p>Hi, {name}.</p>;
```

- Compiler can now check that this is valid HTML
- {…} replaced with string value of expression

JSX Gotchas

- Put (..) around HTML if it spans multiple lines

- Cannot use `class="btn"` in your HTML
  - `class`, `for`, etc. are reserved words in JS
  - use `className`, `htmlFor`, etc.

- Must have a single top-level tag:
  - not: `return <p>one</p><p>two</p>;`
  - usually fixed by wrapping those parts in a `div`

Problems

This is even better, but it still has problems…

1. Modularity is still poor
   - need to join strings into one big string
2. More boilerplate
   - minimized JS file would change function names
   - need to call `btn.addEventListener` by hand

React

- Regain modularity by allowing custom tags

```
let app = (
    <div>
      <TitleBar name="My App"/>
      <EditPane rows="80" />
    </div>);
```

- `TitleBar` and `EditPane` can be separate modules
  - their HTML gets substituted in these positions

React

- Custom tags implemented using classes

```
class TitleBar extends React.Component {
```

- Attributes (`name="My App"`) passed in `props` arg
- Method `render` produces the HTML for component
- Framework joins all the HTML into one blob
  - can update in a single call to `innerHTML = …`

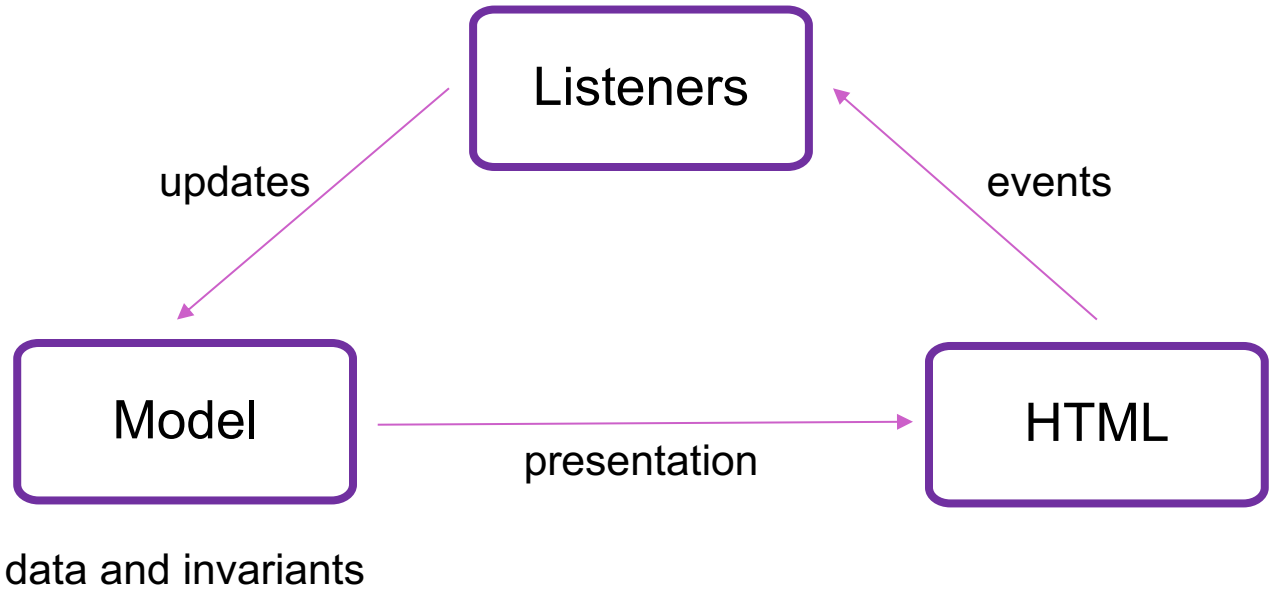
React Example

register-react/…

React State

- Last example was not dynamic!
  - there was no model
  - (why have classes then?)

Structure of a React Application



React State

- Last example was not dynamic!
  - there was no model
  - (why have classes then?)

- Components become dynamic by maintaining state
  - stored in fields of `this.state`
  - call `this.setState({field: value})` to update

- React will respond by calling `render` again
  - will automatically update the HTML to match the HTML produced by this call

Example 5

register-react2/…

Event Listeners

- Recall the issue with "`this`" in JavaScript.
  - **careful** writing `onClick={this.handleClick}`

- Three ways to do this properly:

  1. `onClick={this.handleClick.bind(this)}`

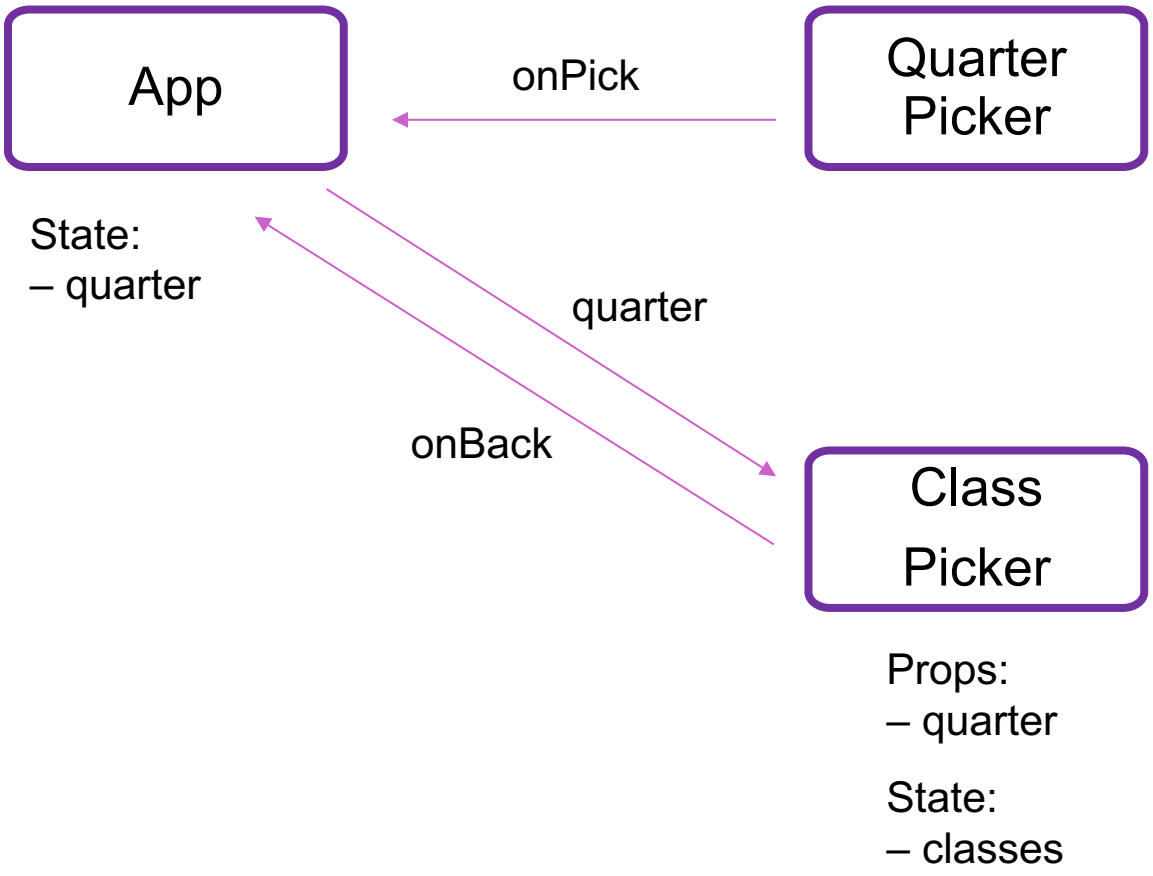
  2. `onClick={(e) => this.handleClick(e)}`

  3. Make `handleClick` a field rather than a method:

     ```
     handleClick: (e) => { … };
     ```

     Then `this.handleClick` is okay. (The homework assignment does this instead.)

Structure of Example React App



React State

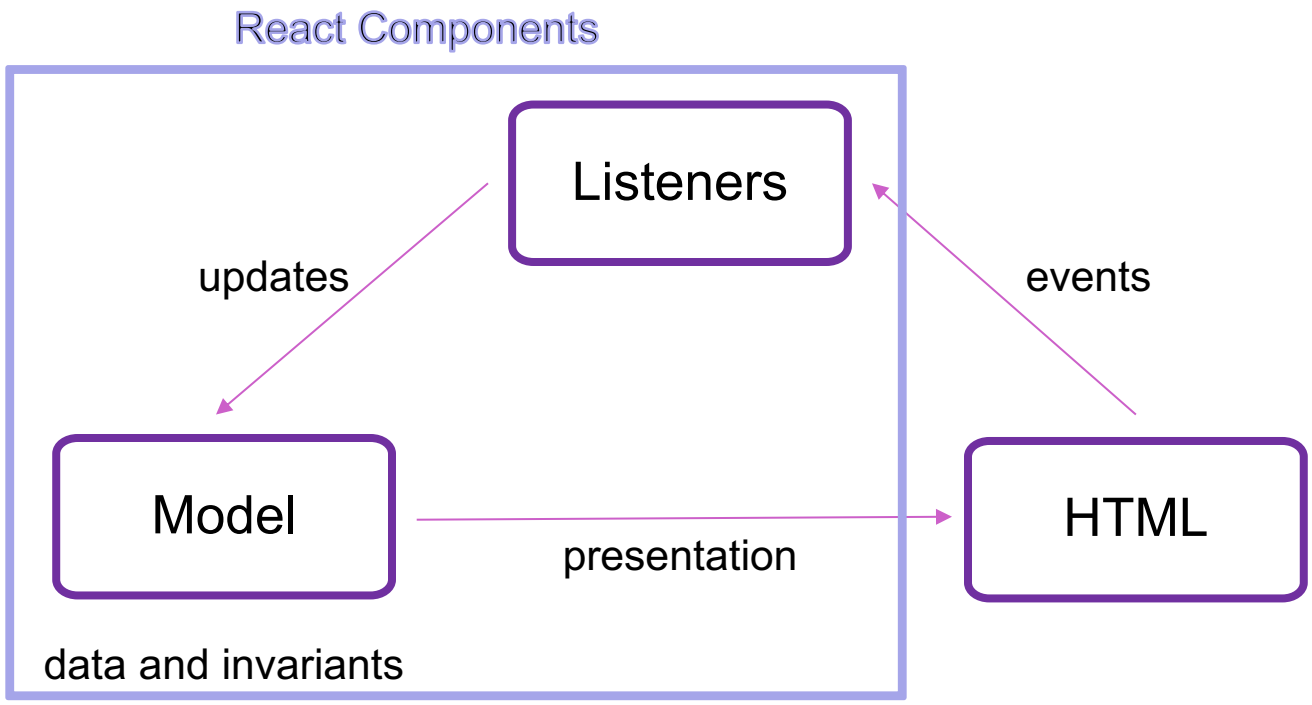
- Custom tag also has its own events

- Updating data in a parent:
  - sends parent component new data via event
  - parent updates state with `setState`
  - React calls parent's `render` to get new HTML
    - result can include new children
    - result can include changes to child props

Splitting the Model

- State should exist in the **lowest common parent** of all the components that need it
  - sent down to children via *props*
- Children change it via *events*
  - sent up to the parent so it can change its state
- Parent's render creates new children with new props

Structure of a React Application



Structure of a React Application

- Model must store all data necessary to generate the exact UI on the screen
  - react may call `render` at any time
  - must produce identical UI

- Any state in the HTML components must be mirrored in the model
  - e.g., every text field's `value` must be part of some React component's state
  - render produces

```
<input type="text" value={…}>
```

React setState

- `setState` does not update state instantly:

```
// this.state.x is 2
this.setState({x: 3});
console.log(this.state.x); // still 2!
```

- Update occurs after the event finishes processing
  - `setState` adds a new event to the queue
  - work is performed when that event is processed

- React can batch together multiple updates

React Gotchas

- `render` should not have side-effects
  - only *read* `this.state` in render
- Never modify `this.state`
  - use `this.setState` instead
- Never modify `this.props`
  - read-only information about parent's state
- Not following these rules may introduce bugs that will be hard to catch!

React Performance

- React re-computes the tree of HTML on state change
  - can compute a “diff” vs last version to get changes

- Surprisingly, this is not slow!
  - slow part is calls into browser methods
  - pure-JS parts are very fast in modern browsers
  - processing HTML strings is also incredibly fast

React Tools

- Use of compilers etc. means new tool set

- `npm` does much of the work for us
  - installs third-party libraries
  - runs the compiler(s)
